The Northwestern Telephone Exchange Company, which last spring entirely rebuilt its exchange in Winona, Minn., adopting the central energy system, announces an increase in the rates to be charged for service, this increase to be effective on the 1st of November. A corps of canvassers is making a house to house canvass of every residence in the county. The rates so far presented to those seen are practically the same as those charged by the Winona Telephone Company.

It is stated that the Albany, N. Y., Home Telephone Company will not merge with the telephone companies under the name of the United States Telephone Company. It proposes to retain its identity and to continue the policy pursued with such success so far in its career in that city.

A general overhauling and the placing of new equipment has recently been accomplished by the Independent Telephone Company of Union City, Ind.

The Citizens' Mutual Telephone Company of Paris, Ill., was lately formed by the consolidation of 14 Independent telephone systems in that State.

The Kansas City, Mo., Telephone Company is installing a telephone system in Argentine and will shortly have telephones in use there. A central energy system is being put in.

The Aurora, Kan., Telephone Company will build a line to Ames in the near future. The company now has connections with the Concordia Company.

The Bentonville, Ark., city council is considering an ordinance to control and restrict telephone companies.

The Fenton, Mich., Mutual Telephone Company lately received propositions from two telephone companies for the purchase of its system.

C. M. Hoover has been granted a telephone franchise in Calistoga, Cal.

The Waupaca, Wis., Independent Telephone Company has been granted a franchise.

The citizens of Fowler, Col., are about to form a mutual telephone company.

Company Refuses to Join the Trust.

One important Independent telephone system in Oklahoma, the Topeka & El Reno Telephone Company, has survived the consolidation of the Pioneer and the Missouri & Kansas Telephone Companies. The Topeka & El Reno Company practically controls all that portion of Oklahoma south of the Choctaw and west of the main line of the Rock Island Railroad. It began the building of telephone lines and exchanges in that territory prior to the opening of the Kiowa and Comanche country. The company is capitalized at $200,000, of which $140,000 is paid up. On a flat rate schedule of $2 for business and $1.50 for reidence telephones the company has prospered.

So long as the Pioneer Company was Independent there was a mutual agreement in which both companies were pledged not to invade each other's field. The compact was kept. Since the Pioneer purchased the property of the Missouri & Kansas in Oklahoma the Pioneer has made overtures to the Topeka & El Reno Company looking toward the control or purchase of the latter's holdings. All offers have been declined. The owners of the Topeka & El Reno Company have been careful to issue no bonds, and its stock is held in such a way that a rival company cannot get a controlling interest. If the Pioneer Company should begin building into Southwestern Oklahoma and paralleling the lines of the Topeka & El Reno Company the latter, according to a statement made lately by one of the officers, will begin building into that portion of Oklahoma now occupied by the Pioneer Company.

Long distance service was lately established between the Fort Worth Independent Telephone Company and the Waxahachie, Tex., exchange of the Ellis County Independent Telephone Company. Material is on the ground, and work is being pushed to connect the cities of Fort Worth, Gainesville, Sherman and Denison. Service between these cities is expected to be established within the next 90 days. Work is also in progress on a line from Fort Worth to Dallas. This line will probably be completed this month.

The directors of the Toledo, O., Home Telephone Company at a recent meeting decided to increase the wages of all its operators about 10 per cent. The increase was entirely voluntary and is greatly appreciated by the employes. The directors also declared the customary 1 per cent. quarterly dividend; the books closed October 1 and reopen October 10.

The Twin City Telephone Company has closed a deal for the Maple Leaf Telephone Company of Foley, Minn., and it is reported that a line will be run from Santiago, Sherburne County, to Foley, to connect with the local exchange. The purchase is taken as an evidence that the company contemplates invading territory tributary to St. Cloud.

The Northwestern Telephone Exchange Company has acquired a controlling interest in the Albert Lea, Minn., Telephone Company. This takes in the local exchange and for the present shuts out the Tri-State Telephone & Telegraph Company.

Will Perfect Telephone Invention.

Prof. L. I. Blake, head of the Department of Electrical Engineering at the University of Kansas in Lawrence, has been appointed chief engineer of the new submarine signal company which handles his invention for telephoning between ships, using the water as a medium. He made this discovery while a student in Berlin, and has been perfecting his invention. The system is already being used between American warships, and has recently been adopted by the German Government.

The Tri-State Telephone Company has rented offices in Brownsville, Pa., and will soon extend its county service from Uniontown and other parts of the county to Brownsville and other towns in the Monongahela Valley. Connection will be made at West Brownsville with the Union Telephone Company of California, Pa., which will give service at California, Coal Center and other lower river towns. The Tri-State has 12 exchanges in Fayette County, and about 3,000 subscribers.

At a recent meeting of the board of Kitsap County, Wash., commissioners, the Northwest Peninsula Telephone & Telegraph Company was granted the right to use 76 county roads and numerous streets and alleys in unincorporated towns in that county for the purpose of erecting poles, stretching wires and operating and maintaining a telephone and telegraph system thereon. The privilege is given for 50 years. The company now operates the telephone system in Port Orchard, Charleston and Bremerton, as well as to various other places in the county.

The Newcastle, Ark., Telephone Company was lately incorporated by J. L. McDougal, president, and W. J. Dillon, secretary. The purpose of the company is to construct a telephone line from Newcastle to Forrest City. The offices of the company are at the latter place. The capital stock is $1,700.

J. W. Callahan, who recently purchased the Bainbridge, Ga., Telephone Exchange, has begun the work of remodeling the entire system and in a few weeks Bainbridge will have a system the equal of those in most of the large Southern cities. Mr. Callahan invested $20,000 in the new equipment for the system and the work is being pushed as rapidly as possible. The drop flash light system will be used.

A report from Ardmore, I. T., states that the Sulphur telephone system has been sold by C. J. Webster and J. D. Kirby to W. N. Hayes, of Norman, Okla., and J. F. Rumley, of Chicago. The new owners have already taken charge and will make extensive improvements.

The Central Union Telephone Company of Richmond, Ind., has been refused permission to lay conduits in the streets until all the companies using wires are prepared to do the same thing.

A dozen farmers of Vera Cruz and Limeport, Pa., will construct a telephone line to Hosensack, where it will connect with the present line.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Banning, Minn.—An electric light plant and waterworks are to be established in this city in the near future.

Elk Rapids, Mich.—The council has granted a franchise to Arthur McMillan, of Toledo, O., for an electric lighting plant.

Hopkinsville, Ky.—John H. Bell, Jr., has secured a franchise to build and operate an electric light and power plant.

Humble, Tex.—The electric light and power plant at this place was lately destroyed by fire. The loss is estimated at $10,000.

Knoxville, Tenn.—The Consolidated Railway & Light Company of Philadelphia, Pa., may ask this city for a franchise to erect a gas and electric lighting plant here.

Little Chute, Wis.—The Kaukauna Electric Light Company has been granted a 10-year franchise to furnish commercial lights in this village.

Loudonville, O.—The electric light plant in this place, owned and operated by the city, was lately destroyed by fire.

Martin, Tenn.—The city officials will put in about $1,300 worth of improvements on the water and electric light plant.

Midland, Md.—J. C. Brydon, superintendent of the Consolidation Coal Company, will erect a plant at Ocean Mine No. 1 with power enough to supply light to this town and surrounding places.

Mooresville, N. C.—The citizens will vote October 10 on the issuance of $10,000 in bonds for the establishment of an electric light plant. Address the town clerk.

Port Washington, Wis.—The citizens have voted for the issuance of $75,000 bonds for the installation of an electric lighting and waterworks plant.

Rockford, Ill.—The stockholders of the Central Heat & Power Company have decided to double the lighting plant and a new 500 hp. engine and generator will be purchased.

South Bend, Wash.—Articles of incorporation of the Chinook Light, Power & Water Company, have been filed at the county auditor's office. The capital stock is $10,000. The incorporators are James T. Pollock and J. G. Kelly, of Portland, and Albion L. Gile, of Chinook.

Syracuse, N. Y.—The Auburn & Northern Construction Company of this city has been formed to construct railroads, electric light plants, etc. Its capital stock is $5,000, and incorporators, Harold C. Beatty, Harry J. Clark and Claude Constead, all of this city.

Theresa, N. Y.—The contract for the construction of the dam and the power house foundations for the municipal electric light plant of this city has been awarded to Contractor E. D. Bennet, of Pulaski.

West Brooklyn, Ill.—William Mink, of Paw Paw, expects to install an electric light plant here soon.

Woodstock, Ont.—By a vote of 42 to 165, the by-law to raise $50,000 to expend on improvements and extensions to the electric lighting and waterwork plants of this city was recently carried by property owners here. The adoption of the by-law means that new pumps, reservoirs and generators will be installed at a cost of $50,000.

STREET RAILWAYS.

Ardmore, I. T.—C. H. Barrett, of Kansas City, is in this city looking over the field in connection with the building of an electric line.

Athens, Ga.—It is entirely probable that the movement to build an electric railroad from this city to Carnesville will be revived and carried to completion at an early date.

Austin, Tex.—The charter of the Fort Worth & Mineral Wells Electric Railway Company of Fort Worth and Mineral Wells has been filed here. The capital stock is $250,000. This company will construct and operate an electric line between Fort Worth and Mineral Wells to carry passengers, express and freight. The incorporators are Cicero Smith, D. M. Howard, H. N. Frost, E. J. Waldron, Albert Stevenson, all of Palo Pinto County.

Bartlesville, I. T.—A company has been formed in this city to build and operate an electric line between this city and Dewey.

Bradford, Pa.—A new trolley line will be built from this city to Eldred. John C. Mills, a well known business man of Duke Center, is one of the projectors.

Durand, Mich.—J. D. Leland, cashier of the First National Bank and his associates, have accepted the franchise for an electric railroad franchise which was granted last February. It is announced that work on the line will be commenced at once.

Elgin, Ill.—Work on the new Elgin-Belvidere electric line is being pushed rapidly.

Helena, Ark.—A project to build a trolley line from this city to Brinkley is under consideration here.

Johnstown, Pa.—By recently securing charters at Harrisburg, the first steps were taken for the construction of four new electric street railways in Cambria County. Work is expected to start as soon as the contracts can be let.

Marysville, Cal.—The location survey for the electric railroad John Martin proposed to build to connect this city with Auburn, Grass Valley and Nevada City, is almost completed.

Norfolk, Neb.—Local capitalists contemplate building an electric line from this city to Emerson.

Rochester, N. Y.—The Holland-American Construction Company of this city was lately incorporated to construct railways, power and electric plants, canals and other public works. The capital is $1,000,000, and the directors are Newcomb Carlton, New York; George C. Smith, and Walter D. Uptegraff, Pittsburg; Joseph H. Lukach, London; John N. Beckley, Charles H. Palmer, J. George Kaelber, John F. Alden and George C. Buell, of this city.

Saginaw, Mich.—The Saginaw Southwestern Electric Railway Company has increased its capital from $50,000 to $100,000,

St Clairsville, O.—The citizens have been discussing the proposed electric railway from Bellaire to this city.

Steubenville, O.—The Steubenville & Wellsburg Traction Company has been incorporated with a capital of $10,000 by D. J. Sinclair and Joseph Carnahan.

Waterloo, Ia.—An interurban electric line between this city and Marshalltown is said to be a certainty.

POWER PLANTS.

Brandon, Man.—A syndicate composed of Canadian and American capitalists intend developing the water power on the Assiniboine River here. The intention is to erect a large power house and plant.

Harrisburg, Pa.—The board of directors of the Central Pennsylvania Traction Company at a meeting recently authorized the construction of a new power plant to cost from $200,000 to $250,000. The new plant will be erected upon the site of the present one. The question whether steam turbines and an alternating current with sub-stations or reciprocating engines with direct current, and ample feed wires, are to be adopted, is left for determination by a special committee of the board appointed to supervise the erection of the plant.

Reading, Pa.—The United Traction Company will build a $1,500,000 power plant along the Schuylkill River in this city.

Utica, N. Y.—Preliminary work has been started by the Hudson River Electric Power Company on the construction of a transmission line to convey electric power that will extend from the great power plant on the upper waters of the Hudson River to this city. When completed the line will be one of the longest in the East, extending a distance of nearly 100 miles. It is expected that it will be completed by the middle of next summer.

BIDS WANTED.

Fortress Monroe, Va.—Sealed proposals for furnishing and installing the fixtures for electric lighting in 30 sets, bachelor quarters, three double sets, officers' quarters, and the Post Exchange and Gymnasium Building here will be received until October 16. Bids should be marked as such on envelope or outside wrapper. Address R. H. C. Kellton, Quartermaster.

New York City.—Sealed bids or estimates will be received by C. B. J. Snyder, Superintendent of School Buildings of the Department of Education, corner of Park avenue and 59th street, until 11 A.M. on October 9. No. 1 for installing electric equipment in the addition to and alterations in Public School 27, on the southwest corner of Nelson and Hicks streets, Brooklyn. The time of completion is 60 working days. The amount of security required is $5,000. No. 2 for installing electric light wiring and fixtures in the fourth story of Boys' High School, Marcy avenue and Putnam avenue and Madison street, Brooklyn. The time of completion is 30 working days. The amount of security required is $800.

Washington, D. C.—Sealed proposals in duplicate will be received by the Department of the Interior at the office of Elliott Woods, superintendent of the United States Capitol Building and Grounds, until 2 o'clock P.M. November 8, for electric lighting fixtures for the House and Senate wings, United States Capitol Building. Specifications and general information will be furnished on application. The right is reserved to reject any or all bids or to accept parts or any or all bids, and to waive technicalities.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16¼@16½c.; Lake 16¼@16½c.; casting, 16@16¼c.

It is stated that the Widener-Elkins Syndicate is buying Brooklyn Rapid Transit stock.

The Syracuse (N. Y.) Rapid Transit Company has increased its dividend rate from 4 to 5 per cent..

The stockholders of the Coney Island & Brooklyn Railroad Company will hold their annual meeting on October 16.

The New York & New Jersey Telephone Company has declared the regular quarterly dividend of 1½ per cent., payable October 14 to holders of record October 5.

An official of the Pennsylvania Electric Vehicle Company says: "Our sales for the current year have been very good and we are able to show a moderate improvement in earnings over those of last year."

The Hudson River Telephone Company of Albany, N. Y., has declared the regular quarterly dividend of 1½ per cent., payable October 14. Books close October 5 and reopen October 16.

It is current gossip that Kuhn, Loeb interests have recently bought 10,000 shares of Brooklyn Rapid Transit and that interests identified with the Morton Trust Company have also bought a like amount.

Plans are being formulated for the organization of the Rochester & Southern Electric Railway Company, with a capital stock of $5,000,000, to construct an electric line from Rochester to Elmira, N. Y.

For September Brooklyn Rapid Transit Company's gross earnings increased $5,200 per day over September last year, and gross earnings for the September 30 quarter increased $500,000 over last year.

A dispatch from New Haven, Conn., says the Consolidated Railway Company has ordered 57 cars of the latest type and 14 snow plows for the different divisions of the electric system. The new equipment will cost about $400,000.

The Rome and Oneida (N. Y.) Electric Railway Company was incorporated at Albany on Monday, with $350,000 capital stock, to construct a street surface electric railroad 13 miles long from Rome to Oneida. The directors are T. L. Hill and C. C. Goodwin, New York; E. F. Lally and G. V. Lally, Detroit.

Electric Company of America, Philadelphia, in eight months of this year shows a gain in net profits of $100,000 over last year. The company is now reported earning at the rate of nearly 12 per cent. on its stock and it pays 7 per cent. in dividends. Vice-President Catherwood says the outlook is excellent.

William S. Reed, representing a syndicate of capitalists, has agreed ts purchase the active property of the Chicago Electric Traction Company. The consideration is $200,000 in stock of the reorganized company and $650,000 cash. The road will be extended to Kankakee, Ill. When it is completed the syndicate may buy back the $200,000 stock for $100,000 cash.

A dispatch from Montreal, Canada, says the shareholders of the Mexican Light & Power Company, at a special meeting held at the Bank of Montreal Friday, ratified the plan of the board of directors to increase the capital stock of the company from $12,000,000 to $16,000,000. The additional $4,000,000 will be used to secure control of two of the largest lighting companies in Mexico.

EDITORIAL NOTES.

German and American Electrical Workers.

The foreign worker arriving at American shores is struck by the magnanimous salaries paid to those of his class. He is frequently appalled, however, by the cost of the good things he is accustomed to at home. This applies particularly to the German engineer, draughtsman or artisan. It applies to some extent to the workers of other nationalities—the Austrian, French, Italian or English. But the case usually presented, is that of the German and American. The question frequently arising is that of high wages and a higher cost of living. To the German worker, full of the traditions of the old country, the living wage is an all important issue. If it is not forthcoming he emigrates; in this respect the English worker differs. Emigration to him consists only in leaving England for another colony over which her flag waves. English workmen do not seek American shores in either the numbers or with the same spirit as the German. But the weightier matter, rising in greater and greater prominence, irrespective of the national origin of those working, is that of the returns for labor and the cost of living. A report reaching this country from Berlin, states that the employers of the Allgemeine and Siemens-Halske Companies have locked out about 10,000 of their employes. This lockout affects the cable works of the Allgemeine Company on the Upper Spree, and the dynamo works of the Siemens-Halske Company at Charlottenburg. Trouble between the great electrical companies of Berlin and their employes has been brewing for some time. The workmen in several departments of the two chief companies have been the leaders in this move. The men say the cost of living has risen so high, owing to the high price of wheat and other articles, that their wages are not sufficient. At least 60,000 men are employed by electrical companies in Berlin, and their future is as much related to the outcome of this agitation as the active parties engaged. A German electric lockout, conducted on this basis, offers room for a comparison. While the discussion of economic questions is not the purpose of these columns, still the consideration of the welfare of our own electrical workers is a matter of vital importance. The Germans, it seems, with their thrifty mode of life, are actually appealing for more necessities. They cannot live with what they now receive. Are the prices paid for German machinery too low, or is the German too willing to work for a scanty stipend? If this last is the case, combination will effect great things. If the former, the price of machinery must be raised. In America the wages paid bear a distinct relationship to the American way of living, the selling price of the generator or other form of electrical apparatus, and the rainy day, always held in prospect. Reinforced, as the ranks of the German workmen are by the peasant element from the interior and the South of Germany, their standards of living are lower than our own. If they demand more of their employers, it is because they cannot subsist on what they get. Their wages border on the line between necessity and want. It seems that the electrical industries of Germany are in a flourishing condition. For this reason, the plea of the electrical workers is probably more than a delegate's ambition. The electrical worker in this country is by far better off than his brethren abroad. No wonder the German artisan finds a haven of refuge here from the pressure of living he experiences in his own fatherland?

* * *

The Highest Speed of Electric Trains. The theoretical speed of a certain class of motors with no load is infinite. The series wound motor represents this class, and is the type employed to run electric cars for street railway service or heavy traction. Within the city limits speed is regulated by ordinance not to exceed a certain figure, but in the case of a traction system, devoted to passenger and freight service, operating on lines stretching away to distant cities, the conditions are different. It has always been the aim of railroad companies to increase the speed as far as was consistent with safety. All roads preserving a good time schedule and running fast trains have been best patronized by the public. The question, therefore, of the highest speed of electric trains now practical is deeply interesting.

The series motor, when unloaded, reaches a terrific rate of speed. The heavier this machine in rating, in comparison with the weight of the car and trucks, the more nearly is the condition approached of a light load. In other words, though a speed of 80 or 90 miles an hour is given as the rate at which the New York Central trains will run when the electric system is completed, it must be understood that with more powerful motors the relationship of load would thus be reduced and in consequence the speed greatly increased. Speeds of 100 or even 150 miles an hour are perfectly practical at present if a good roadbed and a reliable lubrication are assured things.

* * *

Electrical Design and Art Standards. Observation will quickly remind one of the transformation occurring in the different departments of electrical engineering. The arc lamp, incandescent lamp, generator, switches, and other appliances of electric lighting, have passed through a certain experimental and probationary period. They are no longer the crude looking, clumsy devices originally placed upon the market by early inventors. As an instance of this transformation, the arc lamp, whose weight in the beginning of its history as a street light was so great that a heavy support and hoisting apparatus was necessary to handle it, is now, under the influence of a growing sense of art, embellished and ornamented to a high degree. It is small, light in weight and handsome in appearance. Interior lighting is made much more successful and far more attractive by its use. The incandescent lamp has been reduced in size as well. It is fitted into artistic chandeliers and fixtures. Our ferry boats are brilliantly illuminated by its light, and the more modern of them, plying across the Hudson and the Bay, represent high standards of interior decoration in the fixtures to which these lamps are attached. The generators and motors are also polished and painted to please the eye, and the external form given lines dictated by the same sentiment. The first experimental stage of reduction to practice has been safely passed. The second, a recognition of the æsthetic demand, is rapidly forging to the front.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A monument to Zenobe Theophile Gramme was unveiled at Liege, Belgium, on October 2.

◆

The International Brotherhood of Electrical Workers has unanimously resolved upon a national strike against the New York Electrical Contractors' Association.

◆

The American Society of Civil Engineers is considering the advisability of establishing local sections in various cities.

◆

The Pennsylvania Railroad Company is considering the operation of one of its lines by electricity between its ferry terminal in Camden, N. J., and its electric line in Atlantic City.

◆

President Fish of the American Telephone Company (Bell), who recently returned from a trip on the Continent, makes this statement: "I think, generally speaking, it may be said that the market for telephone securities is gradually broadening." The Independents arrived at the same conclusion some time ago, and that is one of the reasons why they are now struggling to get into New York.

◆

Although the impression has been general that the mileage of electric vehicles is restricted to 25 or 30 miles on one charge of the battery, this idea is fading away with the improvements that are being made over the machines of a few years ago. A rather interesting test in this connection was conducted at Indianapolis recently with a Pope-Waverly road wagon. It was fitted with a 30-cell, nine-plate battery and new cord tires. It was run at intervals without charging from Saturday noon until Tuesday afternoon, and during that time covered 80½ miles, at least one-third of which was over country roads that included many hills. The performance is taken to show the general advancement of the electric, which, together with its characteristic adaptability and perfect safety, is bringing to it a strong following.

◆

A new record in receiving wireless messages has been made by the Government wireless telegraph plant at the torpedo station at Newport. Using a German system, 18 words a minute were received clearly and accurately from Cape Henry, 350 miles; Washington, 325 miles; Philadelphia, 250 miles; Portsmouth, N. H., 150 miles, and several other points where the Government has wireless stations.

◆

The eighth annual convention of the Kansas Gas, Water, Electric Light and Street Railway Association will be held at Kansas City, Kan., at the Mercantile Club House, on October 13 and 14. Mr. R. C. Johnson is president and Mr. I. D. Nicholson secretary.

◆

Upon completion of the Pennsylvania Railroad Company's $60,000,000 tunnel terminal system in New York, the purpose is to run a majority of the electric suburban trains of the Long Island Railroad through the Subway system of this city. To this end it is said a tentative understanding has been reached between officers of the Pennsylvania Railroad and the Interborough Rapid Transit Company.

◆

William D. Mahon, president of the Amalgamated Association of Street and Electric Railway Employes, has issued an address to the members of his order urging arbitration instead of strikes. The address says: "We must bear in mind that in our position as street and electric railway employes we are servants of the public as well as of the company, and that the public is entitled to a certain amount of consideration at our hands. The only means we have of carrying out such a policy is by arbitration, for by submitting our disputes to a disinterested board of arbitration we are able to reach a satisfactory adjustment without having inconvenienced the public or interfered with travel." That's the kind of talk all the labor leaders should indulge in.

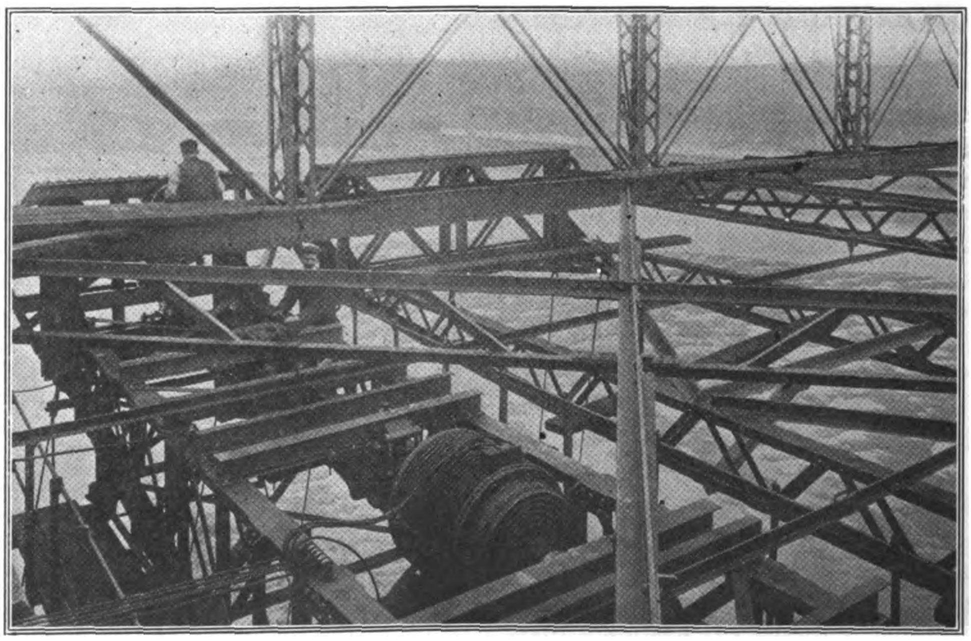
BRIDGES ELECTRICALLY OPERATED IN ENGLAND.

(From our London Correspondent.)

There are not many examples in England of the application of electrical power in the operation of bridges. The first swing bridges to be so worked were the two over the River Weaver at Northwich in Cheshire. These each weigh about 300 tons, of which about 250 tons are carried by the buoyancy of a water-tight pontoon, the remainder being borne on 76 live rollers. The roller is carried on seven cast-iron screw piles. To neutralize the effect of variation of the water level the pontoon is entirely submerged; it is divided into compartments for greater safety. The operations of withdrawing the wedges at each end, and turning the bridge, are controlled from a single cabin. Here there are three large rheostatic controllers, one for each wedge motor, and one for the turning gear. Mather & Platt ammeters and B.T.-H. circuit breakers are provided. The 5 hp. wedge motors are located under the bridge; the wedges are drawn and returned by a right and left-handed screw driven through bevel gear. The 20 hp. turning motor drives, through double helical gear, a drum upon which is wound a 1½ inch steel rope. The ends of the rope pass round, and are attached to a drum fixed to, and concentric with, the axis of the bridge. The motor shaft has a ball thrust bearing, and the turning drum is also carried on balls. A powerful band brake enables the operator to check the movement of the bridge. Two 4 hp. motors are used for working the gates. These motors are controlled from small switch pillars standing by the side of the roadway.

View of Transporter Bridge Connecting Widnes and Runcorn.

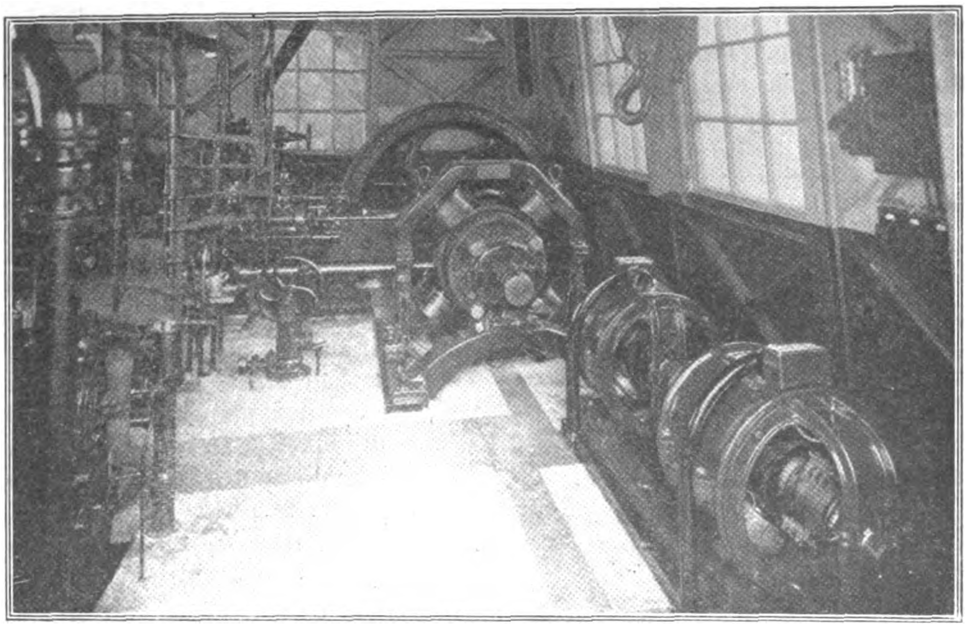
The engineers for the Weaver bridges (Messrs. Mather & Platt, Ltd., of Manchester), who have specialized in this particular line of late, have also recently electrically equipped a rolling bascule bridge at Barking. Experience obtained in these directions was of great assistance in electrically operating transporter bridges, designed on similar lines to that at Rouen. The 1,000 ft. span Transporter bridge over the River Mersey, between Widnes and Runcorn, is the most recently completed example. It has been erected to the design of Mr. John J. Webster, M. Inst. C. E. of Westminster, and the electrical equipment was carried out to the joint design of that gentleman and Dr. Edward Hopkinson. Accompanying this article we show several views illustrating the bridge, its structure and the electrical plant.



The Widnes and Runcorn Bridge, Showing Equipment and Construction.

The engine house is erected within the left hand tower on the Widnes side of the river, and contains the whole generating plant, which comprises two Crossley gas engines of 75 B.H.P. each; the cylinders are 16 inches in diameter, with a stroke of 21 inches, the speed being 210 revolutions per minute. The gas is supplied from the Widnes town gas mains. The engines are fitted with the usual silencers and water-cooling pipes, the water supply being obtained from a large tank fixed at the top of the engine house. A Mather & Platt multipolar dynamo of 48 kw. capacity and capable of giving a continuous output of 90 amperes at a pressure of 525 volts when running at 210 revolutions per minute is direct coupled to each engine. The engine house also contains a booster for boosting the pressure when charging the accumulator, and also for maintaining the voltage on the line and equalizing the load on the generating dynamos. The accumulator is placed in a room above the engine room, and consists of 245 chloride cells, of a capacity of 90 amperes for one hour. The cells are mounted on insulators carried on suitable stands. In the corner of the engine room is the switchboard arranged with three panels; one for the dynamos, with the necessary main and regulating switches and measuring instruments; the second for the battery and booster, and the third for the feeding and lighting circuits.

From the switchboard two main supply cables are led up by the tower and across on to the main girders of the bridge, where they are attached to two overhead



Engine House of the Widnes and Runcorn Bridge.

T-shaped conductors, which are carried by insulators below the cross girders of the bridge, and from which the current is collected by trolley arms, and thence passes down to the controlling apparatus in the driver's cabin, placed on the top of the transporter car. The regulating apparatus consists of a circular type controller by means of which the starting, regulating and stopping of the motors on the traveling trolleys is effected. From the controller cabin the wires are led straight up to the motors fixed on cross girders connecting the pair of trolleys, which run on each of the continuous main girders of the bridge. The motors are of the Mather & Platt steel clad entirely inclosed type, to develop 35 B.H.P. each with a 500 volt current; they drive by means of gearing and shafts the two driving wheels of the trolleys, and are arranged also to act as brakes for stopping the car. The control cabin also contains a small switchboard with the requisite switches and instruments for the information of the driver.

The bridge is lighted electrically throughout, by means of five arc lamps in each of the four lanterns at the summits of the towers; incandescent lamps in standards on the approach roads on either side of the river, as well as the necessary lights on the car itself, and in the waiting rooms and offices on the landing stages.

Another interesting example of an electrically worked transporter bridge is that which has been constructing for some time, and is now very near to completion, spanning the River Usk, and connecting the two parts of the borough of Newport (Mon.), in Wales. The principle of electrical operation is different from that obtaining in the cross-Mersey bridge above described, for the steel wire ropes are wound on a drum which is worked by motors placed on the western shore. The trolley for the Widnes-Runcorn bridge is about 77 feet in length, with 16 running wheels each side, it carries a 55 foot transporter car; the Newport traveling frame is 104 feet long, with 60 wheels in all, and its transporter car is 33 feet long. The Newport bridge has been described as really a suspension bridge carrying on its underside lines of rails, on which will run a truck from which is hung a platform or car at the level of the brakes of the river. It is said that the car with its load will weigh 117 tons; special attention has had to be devoted to the possibility of high winds being encountered.

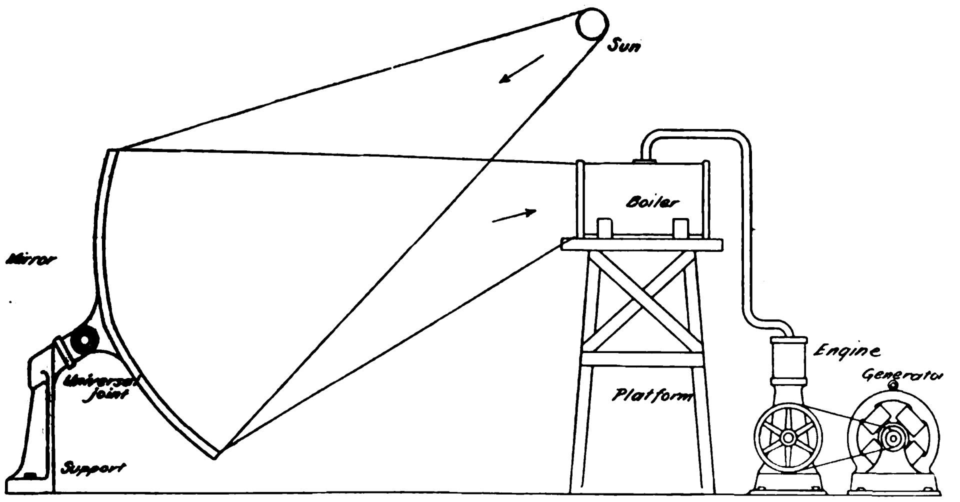
LIGHT, HEAT AND POWER PRINCIPLES.—III.

BY NEWTON HARRISON, E. E.

Power from the Sun.—Although it is not a difficult proposition to prove that all forms of energy known originated in the sun, as far as the solar system itself is concerned, it is of great interest to observe the trend of the efforts made to utilize the sun's rays directly. Ericsson was among the first to advance the idea of the sun motor. By this is meant an engine, so constructed that the action of the sun's rays will heat a steam generating section and thus develop power and rotation. In fact the engine is simply a specially constructed steam engine, the principal part, the boiler in this instance, representing the focus of such of the sun's rays as are gathered up by specially constructed mirrors. It is obvious that the amount of heat transmitted by the sun reaches into figures almost beyond computation. By this is meant the heat energy, not the light, though both can be categoried on this basis. Light is the one item which, so far, cannot be either transformed or stored, as may other forms of energy. The only illustration of this action widely known is that of the plant in manufacturing chlorophyll by the action of light. In this respect because coal is a product of vegetation and vegetation a consequence of light energy being absorbed, coal itself becomes in this sense stored sunlight. The action in this case is one in which light acts as an agent in producing changes in the chemical constitution of vegetal matter.

The utilization of the sun's heat directly by means of concave mirrors, which focus the heat rays, which direct them upon a boiler, which generates steam, which develops rotation by means of an engine, which gives power for driving a dynamo, and which finally permits the storage of electrical as chemical energy in storage batteries, is an illustration of the different channels through which energy can pass before emerging in the form in which it is to be finally utilized. In this instance, at night, the current could be employed for lighting, and thus a certain percentage of the original ether waves again transformed into light and heat.



Method of Utilizing the Sun's Heat for Generating Electricity.

Estimates have been given of the amount of energy radiated by the sun upon a square foot or yard of the earth's surface. It is unnecessary to state that the light is of a brightness unsurpassed by the most brilliant sources of illumination at present in service. Depending upon the position of the sun's rays, whether at early morning, noon or later, the degree of heat and consequently the energy available at a given location would vary. At the equator it might rise to ¼, ½, 1 or more horse power per square yard. At the Tropics of Cancer or Capricorn it would be less, until the temperature zones were reached, where it would be fairly uniform. The great Sahara Desert represents in this respect a source of power as difficult to measure as the tidal or wave forces of the world. At the low estimate of ¼ horse power in heat energy per square yard for 5 hours a day, this desert would yield from a strip 100 miles in length by 100 miles wide the following:

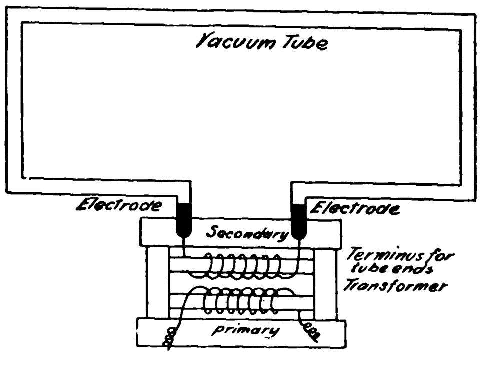
100 miles = 5,280 ft. × 100 = 528,000 ft.
100 miles × 100 miles = 528,000 × 528,000 = 278,784,000,000 sq. ft.
1 sq. yard = 3 × 3 = 9 sq. ft.
278,784,000,000 ÷ 9 = 30,976,000,000 sq. yards.
At ¼ hp. per sq. yard 30,976,000,000 sq. yards produce ¼ × 30,976,000,000 = 7,744,000,000 hp.

For 5 hours the output would be 38,720,000,000 horse power hours.

Vacuum Tube Lighting—A form of lighting which offers some relief from existing methods, in that no actual incandescence of solid matter takes place, is found in the vacuum tube. The usual method of producing light, is to heat to whiteness a certain body of material, usually carbon, and from the radiation thus secured obtain enough light for practical purposes. In burning ordinary illuminating gas, a flame consisting of millions of carbon molecules heated to comparative whiteness, creates the illumination so widely employed. In the use of acetylene, the gas is also capable of producing an incandescent screen of white hot material; but a whiter light due to a higher temperature results. In the Welsbach burner, the heat of the flame is increased by permitting air to enter at the base, and produce a Bunsen flame, which plays upon a screen of rare oxide composing the mantle.

The incandescent lamp is an obvious case of the electrical energy producing heat directly in the filament. The principle, that in proportion to the resistance of the conductor, however good or bad, the energy is degraded into heat, holds true here in a striking manner. The effort is made to degrade all of the energy, the carbon filament by its resistance can transform into heat. From the heat thus produced, the amount of light, variously rated as 16 or 32 candle power, as a usual thing results. But the carbon is the form of solid matter upon which the current operates, heating it, as in the gas or acetylene flame, and secondarily producing light. The arc lamp is a similar instance of where the arc formed between the carbon terminals is composed of carbon molecules, which permit the current to jump across, and in so doing are so raised in temperature that the characteristic dazzling brightness appears. The screen in this case is a mass of carbon particles, probably molecular, heated to vivid incandescence, as in the previous cases referred to. The vacuum tube system of lighting, as now in evidence, consists of a long glass tube of two or three inches diameter, and 10, 20, or even more than 50 feet in length. This tube contains either a partial vacuum or a gas of secret nature, but capable of transmitting the energy imparted to it from end to end. The tube is supplied at both ends with electrodes, which impart the electricity to the gas or remaining air contained within. The ensuing process is of a different character to those outlined. The gas molecules become the carriers of the energy, and being charged act in every respect like other light bodies affected by static influences. The individual charges are sufficient to cause extreme repulsion and agitation among the molecules. They move backward and forward with extreme rapidity, colliding frequently. The extent of the collisions is in some respects a measure of the amount of light produced. Thus, the entire problem of vacuum tube lighting resolves itself down to a case where the original energy is utilized to create free molecular motion over a large path, with the average result that a great number of impacts take place between the carriers. The greater the number of moving molecules, and the faster they move, the greater the number of impacts and the greater the degree of illumination resulting.

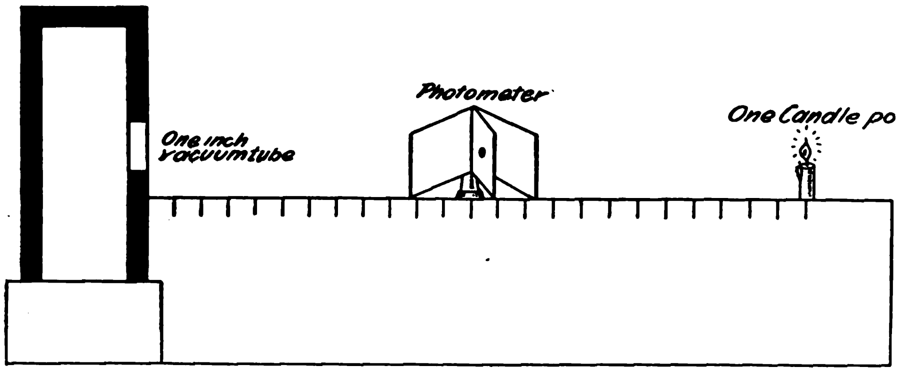
This device is placed around a room, at about the meeting of the wall and ceiling, as one long glass tube, whose two ends enter a box communicating with the source of electric current. The current used is alternating, and is transformed until it reaches a high potential. It is obvious that the potential in this case must bear a direct relationship to the length of the tube. The longer the vacuum tube, the greater the pressure re-



General Principle of Vacuum Tube Lighting, Showing Use of Transformer.

quired to cause a uniform degree of illumination to appear.

Amount of Light per Inch of Tube.—The system calls for the use of a photometer, by means which light measurements are taken of any inch length of the tube. This device gives such results that the failure of the tube to render a normal amount of light is readily detected. In this system a method of joining the glass has been developed, by which it may be lengthened, reduced or repaired with facility. Another feature is one by which it can be exhausted or readily resupplied with the gaseous constituents necessary for the production of light. In all systems developed on these lines the integrity of the vacuum is of first importance. Unless it is preserved the candle power will vary with every change of this kind. At the end of a given length of run the advantages consist of the following: First, it is not necessary to reinstall new lighting apparatus to replace the old; second, it is claimed that the rehabilitation of the system is not a matter of great expense; third, the form of illumination is such that the various degrees of light are admirably mixed in the proportions which insure an agreeable light impression; fourth, because no actual wear takes place of any particular part, the tube may be readily and permanently adapted to the walls of the room, hall, theater or place of worship. The cost of the first installation is fixed; changes in the system would only amount to a new distribution of the light; fifth, the light within the tube is not of an intensely brilliant character, but subdued and non-irritating. It deserves the name given it—artificial daylight.



Method of Getting Candle Power of one inch of Vacuum Tube.

Efficiency.—The power consumed is not in excess of that required for the incandescent lamp system. Per unit of light, the watts required range from 3 to 4, that is, per candle power. The incandescence of the gas particles within the tube, brought about by their motion, may eventually reach a point, by the use of a particular gas, where very little power will excite intense agitation. The elimination of heat is accomplished more thoroughly in this system than in any other in vogue. Heatless light, if properly produced, would mean an economic revolution. A gas jet gives about 1 per cent. or less return in light from the gas consumed. This means a waste of over 99 per cent. of the gas, as far as this object is concerned. A 16 cp. jet taking 5 cubic feet per hour would therefore give 99 × 16 = 1,584 cp. at an efficiency of 100 per cent. Light is therefore wasted to an immense degree, because the present methods are primarily heat instead of light-producing. Comparing the various sources of light gives the following:

COMMON ILLUMINANTS.

First—Torch of resinous wood as a source of illumination, approximately 1 hp. per 16 cp.

Second—Candle made of wax such as paraffin, approximately $\frac{3}{4}$ hp. per 16 cp.

Third—Kerosene oil lamp, approximately $\frac{5}{8}$ hp. per 16 cp.

Fourth—Lamp using illuminating gas, approximately $\frac{1}{2}$ hp. per 16 cp.

Fifth—Welsbach mantle, approximately $\frac{3}{8}$ hp. per 16 cp.

ELECTRICITY.

Sixth—Incandescent lamp, approximately $\frac{1}{10}$ hp. per 16 cp.

Seventh—Vacuum tube lighting, approximately $\frac{1}{10}$ hp per 16 cp.

Eighth—Arc lamps, approximately $\frac{1}{100}$ hp. per 16 cp.

The above figures are arbitrary, but they present a relative view of the amounts of energy consumed to give light. The amount of heat in the carbon when oxidized, considered as a definite amount of energy, covers the first five cases. Those that follow use electricity; if the power price paid for this is estimated from the fuel itself, then the energy consumed in producing electric light would be large in spite of the use of improved and expensive machinery.

TWO LABOR-SAVING DEVICES.

BY W. H. WAKEMAN.

Fig. 1 represents a device for unloading and storing fine coal, coal dust, etc., which has proved very successful in practice. A belt is run over four pulleys, as shown, and power for driving it at a high speed is supplied by an electric motor, located in a small building to protect it from flying pieces of coal. There are no cleats or buckets on this belt, yet the material is carried swiftly upward, partly by the strong draft of air created by the belt moving so rapidly through an inclosed space. The upper pulley is about 40 feet above the ground, in order to permit of unloading several car loads of coal without trimming it.

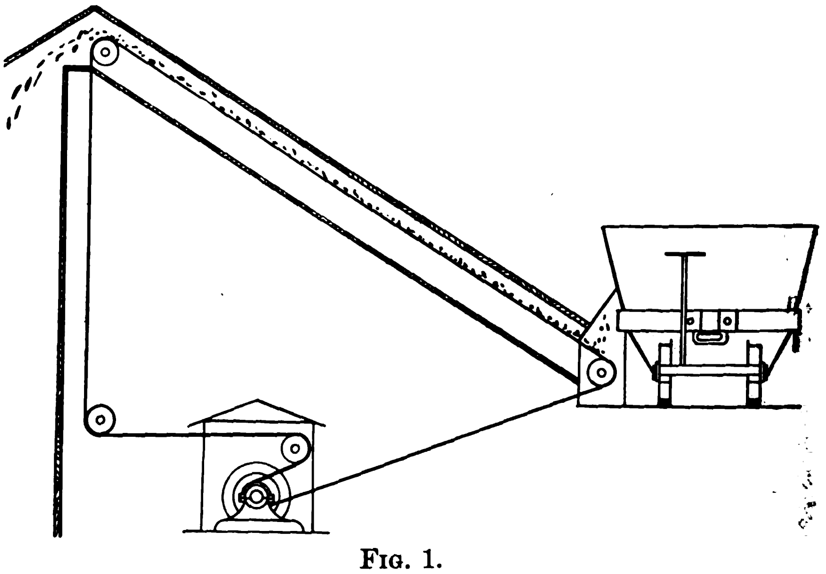


Fig. 1.

Fig. 2 represents a device invented by a working engineer for the purpose of unloading oats and delivering them to his employer's barn. As many horses are used by this firm the work of unloading a car load of oats frequently was quite an item of expense. The barn is several rods distant from the machinery used in its regular business, therefore it was not considered practical to use any device requiring belting and shafting, but use of electric motors in various parts of the works suggested the idea of using one for this purpose, as it was a very simple matter to run wires to and from any point desired.

The operation is as follows: A car filled with oats is run into the yard on a private track and placed so that when a small opening is made at the bottom of a temporary door that is provided for such places oats will flow out into a hopper, as shown. They are thus conducted to a spiral conveyor 2, which carries them under a driveway to the bin 3. A bucket elevator next raises them to another bin 4, out of which they are taken by another spiral conveyor 5, and delivered to a large bin in the upper story of a storehouse where they are kept until wanted.

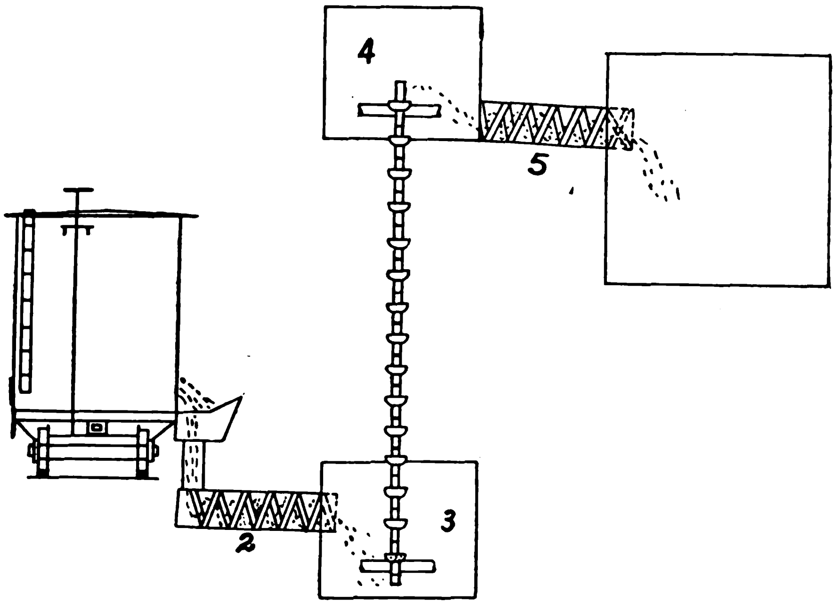

FIG. 2.

Fig. 3 is a side view of the bucket elevator and the motor which drives it. The two spiral conveyors are connected to and driven by this elevator, which is inclosed by means of a wooden housing that prevents the oats from being scattered.

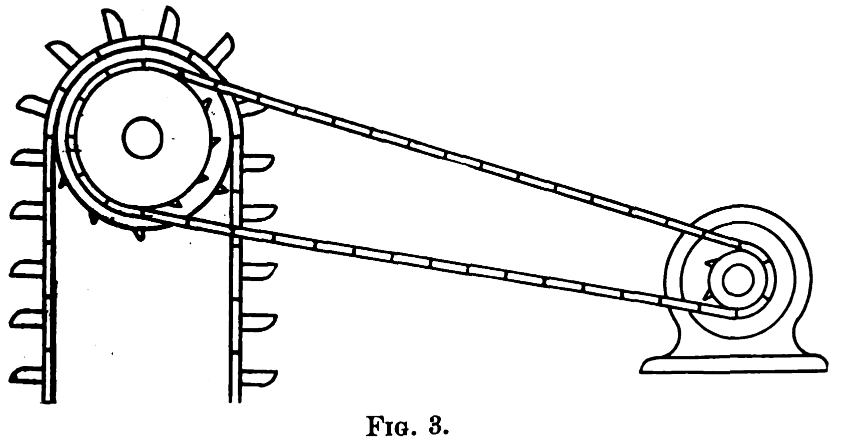

FIG. 3.

The driving wheel on the motor is of the sprocket type, with a chain to fit it, instead of a smooth pulley and belt. This gives a positive motion to the elevator, and as the whole apparatus except the motor, is out of doors, a chain is more suitable than a belt.

Both devices mentioned were installed to eliminate hand labor as far as possible, and in both cases they save about 90 per cent. of the expense formerly necessary to handle the material.

Cars containing these oats are taken from a side track of a steam railroad, and drawn for about one-half mile by an electric locomotive through the streets of a city, where a steam locomotive would not be tolerated. This provides a quiet, clean and convenient means of transportation, making it unnecessary to unload these and other goods at the side track on to wagons, according to old-fashioned methods, and unloading them again at the point of delivery. This makes a saving of expense for carting that is not included in the above statement of percentage saved.

* * *

Oil fuel is used at the central power station of the New Orleans drainage works, which supplies current to a number of electric pumping plants. Sudden heavy rains made it necessary to start up rapidly and oil has proved better than coal.

AN EMERGENCY TRACK BRAKE.*

BY F. F. BODLER,
Master Mechanic United Railroads of San Francisco.

The emergency track brake, hereafter to be described, is used on practically all the cars in San Francisco. While San Francisco is an ideal city for operating street railways in many respects, especially as regards the absence of snow, ice and sleet, yet it has its drawbacks, namely, an enormous number of steep grades. In order to operate safely over these in wet weather and on slippery rails it was necessary to provide another means of braking a car than the wheel brakes. This is successfully accomplished by means of the track brake.

The first experiment with track brakes was made in 1883 or thereabouts, when the Market Street Railway Company built a cable line on Market street. The brake was similar in principle to the present brake. It was placed on the rear truck and operated by a hand lever placed alongside of the grip lever.

In 1893 the Market Street Railway Company consolidated with several other lines and in 1894 commenced to change the motive power of some of its lines from horse and cable to electric. The first cars were of the single truck type, and were equipped with wheel brakes only. It was immediately discovered that an emergency brake was needed, as the cars could not be controlled on the grades, although the tracks were well sanded, and the wheel brakes were powerful enough to lock the wheels. This condition had not been met with on cable cars, as the cars could not go faster than the cable.

In 1895 G. W. Douglas, then master mechanic of the Market Street Railway Company, started to experiment with a track brake on electric cars. Twelve single truck cars were equipped with track brake and operated successfully until 1899. In that year Mr. Douglas reconstructed his brake, and made it applicable to double as well as to single trucks. This is the brake which is now so successfully used in San Francisco.

Primarily the brake (see Fig. 1) consists of a hand lever connected by a brake rod to an arm keyed on a rocker shaft extending clear across the truck. This shaft is connected on each end by means of a short lever, keyed to the shaft, to a connecting link and to a toggle lever. The connecting lever is connected to a lever keyed to a short shaft and to a toggle lever. The shell for holding the shoe is connected to the toggles by means of the heels.

---

*Paper read at the annual convention of the American Railway and Mechanical Association, held at Philadelphia, Pa., September 25-26, 1905.

By pulling back on lever the shaft turns from left over to right, tending to make the short lever assume a vertical position This motion is transmitted to the long lever by means of a connecting lever. The simultaneous parallel movement of the levers causes the toggle levers to assume a vertical position and to force the shoes to the rail. The heels, one on each side of a channel iron across the truck, act as a guide and allow the shoe to travel only in a vertical direction.

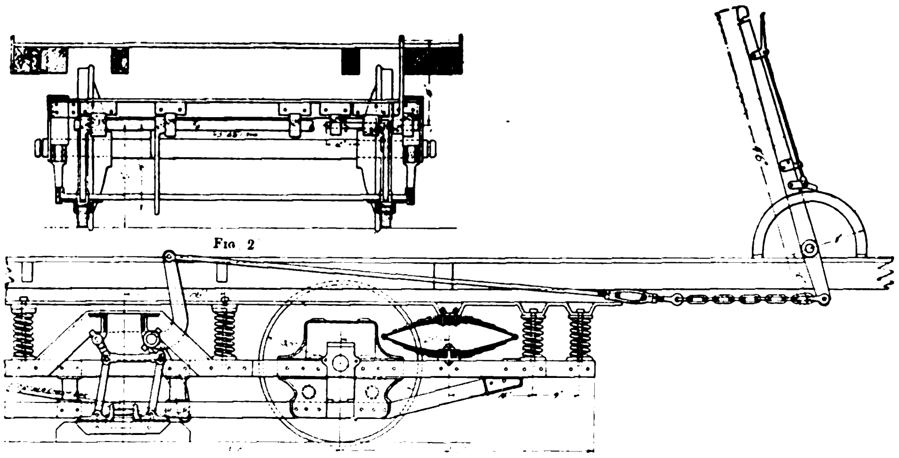

Fig. 1.—Track Brake Applied to Peckham Truck.
Fig. 2.—Sectional View of Same.

A lever with a counterweight attached to it, keyed to the shaft at any convenient position or bolted to the arm, acts as a release.

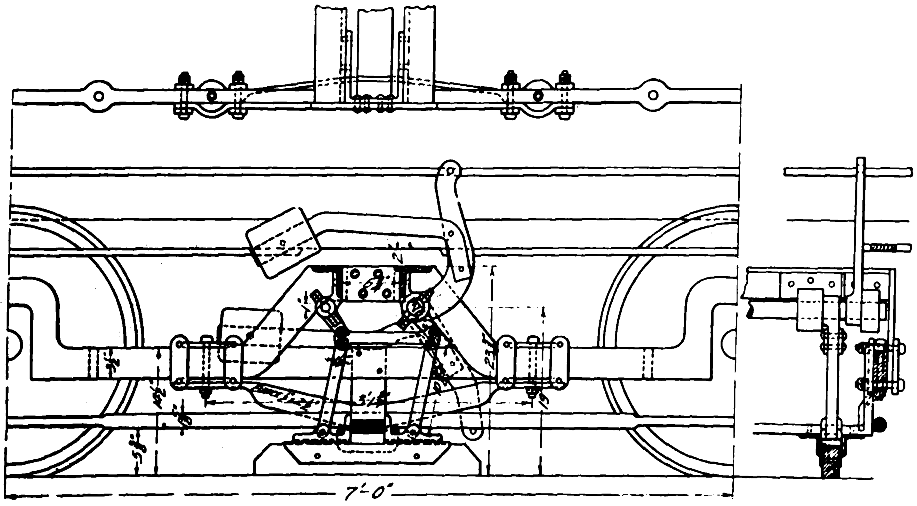

Fig. 3.—Track Brake Applied to Brill Single Truck.

In order to adapt this brake to a Peckham or Brill single truck it is necessary to fasten a flat iron, bent as shown, to the side frames, using the holes on each side of one of the spiral body springs. Two angle irons are placed transversely across the truck and fastened to the bent flat iron. To these angle irons the brass boxes for holding the shafts are bolted. The large shaft is held in position by three boxes, one on each end and one near the arm. The short shaft is held by two boxes, one on each side of the lever.

To operate the track brake from the opposite end of the car an arm is keyed to the shaft, the brake rod being placed under and on one side of the motor, as shown in Fig. 2.

Considerable ingenuity had to be exercised in order to place these brakes on all cars. The arm, for instance, in many cases had to be placed under the seat, the floor having been cut out. With a single truck car the relative position of the arm on the shaft does not make any difference. Fig. 3 shows the brake applied to a Brill single truck.

This brake is placed on double trucks, in practically the same manner as on a single truck, except that each truck has an independent brake, operated from the end nearest the truck. On double trucks the rocker shaft boxes are fastened directly to the tramsom angle irons. The arm has to be placed in the middle of the shaft on account of the swing of the truck.

Fig. 4 shows a Brill 27-G truck, and Fig. 5 a Peckham 13-B-3-S truck with this brake.

Fig 6 shows a standard track brake shoe. This shoe is made of Oregon pine, costs about $.0275 and lasts about one week. The material to be used for shoes was the subject of many experiments. All kinds of wood, all kinds of metal, combinations of wood and metal, and metal with all kinds of inserts were experimented with. For cheapness, general utility and the highest braking efficiency the Oregon pine shoe was found to be the best. The shell for holding the shoe is made in two parts of pressed steel. Two bolts pass through the holes shown in the shell and through the recesses shown in the shoe, not only clamping the shoe by means of the shell, but also preventing the shoe from slipping backward or forward. In order to facilitate the removal of worn out shoes, sections of rail slightly longer than the shoe are sawed off and hinged on the car house tracks. The cars are placed with the shoes over these hinged rail sections, the hinged rail is swung out, and by loosening the two bolts the shoes drop out.

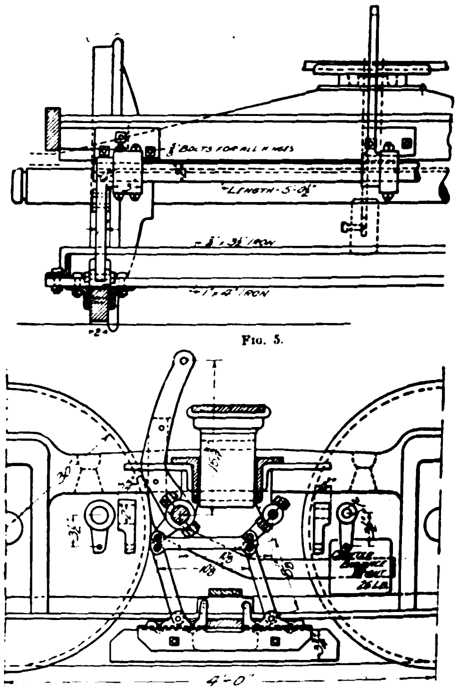

Fig. 4.—Track Brake Applied to Brill G-27 Double Truck.
Fig. 5.—Sectional View of Same.

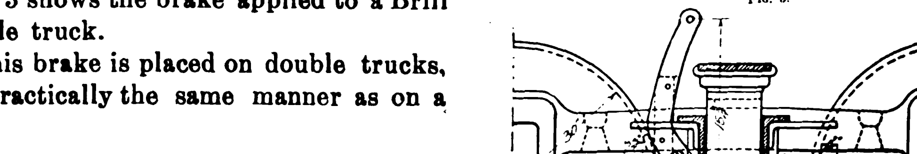

Fig. 6.—Standard Track Brake Shoe.

The time required for replacing four shoes on a double truck car is about two minutes. The shoes can be adjusted when partly worn by inserting wooden shims between the top of shoe and shell.

As seen by various sketches this brake

can only be applied on trucks having outside hung wheel brakes. On double trucks it can only be used when the bolster spring is half elliptic and hung under the side frames. It cannot be used on M. C. B. bolsters on account of lack of room. In fact it requires close figuring to adapt it to the above mentioned trucks, in order to prevent the bolster from coming down on the connecting lever, F.

It has been proved that the brake is most effective when brake levers, as shown in the sketches, are used. The efficiency of the brake is proportionate to the rapidity and force with which the shoe is brought down on the rail. An ordinary ratchet handle with the ordinary spindle is of little use. With a cam on the spindle it is decidedly more efficient.

The strong points in this brake are:

1. Its extreme simplicity.
2. Its high efficiency.
3. Its low cost of maintenance.
4. Its independence of all other brakes.
5. Its being purely a mechanical contrivance.

This brake can readily be operated by compressed air by the addition of a brake cylinder. To the writer's knowledge it has not been operated by that means, however.

Whether it would be as successful in cities where there is much snow, ice and sleet, as it is in San Francisco, the writer would not care to say, yet there does not seem to be any reason why it should not.

It may appear to some that on account of taking considerable weight off the wheels there would be danger of skidding the wheels, yet the number of flat wheels has steadily decreased since these brakes were put on. The reason for this is probably that there is no need of "cinching" the wheel brakes up so tight as there was formerly.

Cars are operated over one 17.5 per cent. grade, four 14.5 per cent. grades, and any number over 10 to 12 per cent. grades.

A single truck car, weighing 10 tons, can be stopped on the steepest grade over which electric cars are operated in the city, in a reasonable distance, by first applying the wheel brakes and then the track brake.

The original intention was to use this brake only as an emergency brake; it has been found so serviceable, however, that it is used almost as much as the wheel brake is. It ought not to be used on curves, switches or crossings, but should it be used, about the only damage resulting would be a split shoe.

CENTRAL STATION DESIGN—AN EXACT SCIENCE.*

An American writer has counseled the youth of his own and succeeding generations as follows: "Aim high; you may not hit what you aim at, but you will shoot the higher for the aiming." It is the privilege of youth to bestow a certain amount of time and energy on the attempt to realize the ideal, and truly the world would be a less interesting place in which to live if this were not the case. When, however, this attitude of mind is exhibited by older men, and in the sphere of business, it lays itself open to adverse criticism, as having strayed out of its legitimate field of poetry or philosophy. Occasionally, even in the prosaic routine of central station work one comes across what would appear to be manifestations of such a tendency, and in this case the results are likely to conduce to unproductive extravagance.

It is still, apparently, an unsettled problem in many minds whether a public generating station shall be regarded strictly on business lines as a revenue-producing concern, or whether it shall be a sort of exhibition, attempting, and often with too great success, to cover the utilitarian with a cloak of æstheticism. Perhaps it is not altogether an advantage that the electrical industry should lend itself so aptly to æsthetic treatment, insidiously flattering the *amour propre* of the members of our local authorities and stimulating them to financial recklessness. There is beauty, no doubt, in a wonderfully swept and garnished engine room, but one would also point out the attractiveness of a favorable balance-sheet.

It is only to be expected that a commercial undertaking of such mushroom growth as is that of the generation and distribution of electrical energy, should provide instances of very varied arrangements resulting from the existence of widely different conceptions as to the object, and the means of attaining that object, of the industry.

Where progress has been so rapid, the interval between ancient and modern must inevitably be of short duration, and the reign of one type of apparatus must be superseded almost immediately, owing to the evolution of newer ideas. So much has this been the case that engineers have rushed from one extreme to another, forgetting in many cases the claims of the older type in the attractions of the new. As a natural result many of our modern power stations (if a station may be regarded as modern after having been in existence ten years) present a most extraordinary conglomeration of plant, mechanical and electrical, of all sizes and shapes.

It is, however, a task of no great difficulty to be wise after the event, to indicate early mistakes in the light of present wider knowledge, and the points proposed for consideration here consist not so much in the choice and arrangement of a type of plant as in a glance at the general aim and the clearness of vision with which efforts have been directed towards it. Neglecting the æsthetic point of view previously referred to, and omitting from our inquiry such stations as exemplify it, we may presume that, in the generality of cases, the main objects sought are efficiency and economy. Let us see how these laudable aims are in course of achievement. We need not go to older stations for examples—our present-day works, now in course of erection, will yield sufficient matter for a short inquiry.

It has been said, and perhaps with some degree of truth, that "consistency is the bugbear of small minds," and one is inspired to hope that herein lies the explanation, difficult to find otherwise, of the very large number of inconsistencies exhibited in the average specification for plant. Who has not seen specifications calling for a definite steam consumption to the second place of decimals, while the methods sometimes selected for ascertaining whether the guarantees have been attained may themselves be questioned as to accuracy within 5 per cent.? Of what conceivable service can be the guarantee of combined efficiency of a generating set, when the only method of checking it involves the use of the indicator, itself subject to a possible error of quite this amount?

Whether or not the engineers responsible for these and other similar anomalies can take shelter under the quotation mentioned, it may be argued that the question at issue is not so much one of consistency as of another commodity of a much more ordinary kind, viz., common sense.

In a recent specification which came under the writer's notice several switchboard instruments of various types were called for. The ammeters reading from zero to 2,000 amperes were required to have an 8-inch scale, and to be accurate within .5 per cent. throughout the range of the instrument. It is a simple calculation to see that the pointer must be true to its position within an amount not exceeding $\frac{1}{25}$ of an inch at all readings, while the needle itself would, in an instrument of this size, be probably nearly $\frac{1}{16}$ inch broad at the point. The voltmeters, and also the wattmeters, were required to come up to an equally unattainable standard, and it would appear that the engineer was not satisfied that his conditions were even then sufficiently stringent. To give still further evidence of misdirected zeal it was specially required that the errors must be inclusive of any temperature effect; and finally the ammeters were carefully placed within 6 inches of large bus-bars, on which the current would vary in intensity from almost nothing up to 4,000 or 5,000 amperes.

---

* Communicated to the "Electrical Review," London.

The precise object of all this is not quite clear, and one cannot help wondering whether some latent vein of humor has not been rather expensively indulged to the discomfiture alike of the instrument maker and also of the station engineer. It is far from our present intention to decry or discredit exactness and accuracy; let us be exact by all means, but it is preferable to exhibit the quality in a rather more sane and less pretentious manner.

If such accuracy could be insisted upon and carried through all departments of central station plant, the works would, at any rate, be efficient, if perhaps somewhat difficult of operation. Unfortunately, however, it is usual to find that such labored exactness in detail has had the effect of allowing very serious objections to occur in the general design of the plant.

The use of the microscope is said to deteriorate the power of the eye for ordinary vision, and it is to be feared that in close attention to the small and comparatively insignificant trifles in the arrangement, the broad lines of design are frequently neglected. It would appear that the sense of proportion becomes obscured, and the close scrutiny which should be given to the *tout ensemble* is bestowed only on some of the component parts.

The question of steam consumption of generating sets was referred to previously in the present article, and may well form the subject of a somewhat fuller consideration, as it is apparently a point far too much labored. Of what advantage is it to the station engineer to possess combined sets where everything is cut abnormally fine to save a quarter of a pound of steam per kw.-hour on test, when his steam range condensation, steam-driven auxiliaries and leakage from joints are accountable for probably far more steam than is consumed by the actual generating plant itself?

It is to be presumed that most stations can generate from their machines at the cost of something like 25 pounds of steam delivered at the engine per unit. On examining the records of these stations, we find that the average amount of steam required per unit throughout the year is in the neighborhood of 50 to 60 pounds, and in some cases considerably higher. To obtain the low steam consumption guarantee, engine clearances must be reduced to the finest possible limit, greatly increasing the liability to serious accident, and also, of course, the first cost, while, as is shown in the foregoing figures, the net gain, if any, to the station is practically negligible.

In the steam turbine particularly, a prime mover for which there is undoubtedly a very wide field in the future, the clearance between rotor and case is made so slight with a view to the exaction of the last fraction in steam consumption, that one constantly hears of blades stripped through too rapid starting. It is difficult to see the use in a power station of a machine which may be very economical when running but which requires half an hour to one hour's warming up before it can be set to work, and in which a comparatively trivial amount of wear in a main bearing is likely to produce disastrous results. One is aware that this is rank heresy to most consulting engineers, but one still holds to the opinion that truer economy would be achieved by sacrificing the steam consumption guarantee, in increasing the clearances somewhat, and being able to take the 5:30 train home and cultivate a peaceful habit of mind.

It should be remembered that the first essential condition in our industry is absolute reliability of supply, and, secondly, economy of production, although we are far from admitting that such a slight sacrifice of efficiency as that contemplated would materially, if at all, affect the latter consideration.

There is another phase of the question which a station engineer rather shrinks from advancing, viz., the wear and tear of the engineer himself. The knowledge that his work is dependent on the maintenance of a 2 mm. clearance is not stimulating to reposefulness. It may be, if the present craze for the highest test-plate efficiency is maintained, that our municipal Cæsars will be exclaiming:—

> Let me have men about me that are fat,
> Sleek-headed men, and such as sleep o' nights;
> Yond' —— hath a lean and hungry look,
> He thinks too much.

Another phase of the subject of anomalies in central station design is introduced in the installation of labor-saving machinery under conditions which cannot possibly result in economy. Such examples as fuel-conveying and elevating gear and mechanical stoking appliances serve to illustrate this. Such apparatus would undoubtedly form a part, and a very valuable part, of the plant of a station operating under ideal conditions, but coming to the actual and dealing with load factors which are very far from ideal, they can in very few cases justify their selection on the score of economy alone. It is difficult to understand the attitude of mind of the councillor who votes for such embellishments, and at the same time provides unremunerative labor for the unemployed section of his constituents.

Instances might be multiplied *ad infinitum* to advocate the cause of simplicity in station design, but enough has, perhaps, been said to indicate a train of thought worthy of more mature consideration.

WRINKLES.*

EDITED BY H. C. ABELL.

A Handy Light for Night Testing.

A handy arrangement for reading instruments at night, when testing transformers and locating trouble, was made by taking an incandescent lamp out of a Christmas-tree set and fastening it to a swinging bracket mounted on a lap board large enough to hold the instruments and record book. The current was supplied by 12 dry cells connected in series and mounted in a box carried in the bed of the wagon and connected to the lamp by lamp cord. This set has been in use for several months, and the batteries do not run out like those of the hand flashlight sets. J. F. DOSTAL, Denver, Col.

Interconnection of Feeder Systems.

In remedying the chaotic condition of affairs in Schenectady by placing the feeders in the business portion underground, we have been compelled to so connect our various feeders that one feeder may furnish current for the one adjoining it in our system of distribution. This was made necessary by the fact that the system of feeding from our old station was overhead, while the system at our new station was underground. It became necessary to start our new station before our underground system was completed, and we were therefore compelled to place current on our primary underground feeders in order to supply our overhead system from the pole taps carried in the cable boxes at various locations.

---

*Paper presented before the National Electric Light Association at its 28th convention, held at Denver-Colorado Springs, Col., June 6-11 1905.

After we had completed the connections between our primary, three-phase underground and overhead feeders, and had placed them in operation, we began to interconnect our overhead system by carrying the three phases of the overhead system from some point near the cable box to some point accessible to the three-phase overhead system of an adjacent feeder in our system of distribution. These interconnecting leads were in some instances a part of one of the two feeder systems to be connected, and in most cases it was only necessary to run a third wire and extend our single-phase lighting primary in order to give us this three-phase accommodation.

Where the two feeder systems were brought together we used an expulsion type of fuse box, testing out the leads to be placed in the fuse boxes with a potential transformer in order to bring the proper phases of the two feeders into the same fuse box. As the drop of our feeder system during the day is very slight, we cut out our feeder regulators, the voltage on all feeders being practically the same. By this arrangement you will notice it was possible for us to feed our overhead system of distribution from an adjacent feeder during the time of light day load by plugging in the fuses mentioned and pulling off the underground feeder from any given section from which we desired to work. This has made it possible for us to make our proper primary underground taps and connections, and develop our underground system and still continue feeding from our new station.

In the business sections of the city we continued to supply current from our overhead secondary, which in turn was supplied with current from our overhead primary, which received its current in turn from the underground primary system. Each day we fed this overhead system from an adjacent feeder and cleared the underground primary feeder in the business sections, thus being able to continue work regularly on an underground system of primary and secondary feeders.

As all of our feeder systems are fed from one common 2,300-volt, three-phase 'bus, it made it possible for us to place these feeders in multiple by testing out the phase with a potential transformer of about 50 watts capacity, using a lamp on the secondary of the same. We find this a much better and safer method of phasing our lines than the old method of using a long piece of fuse and a stick.

L. O. RIPLEY,
Mgr. Schenectady Illuminating Co.

United States Telephone Independents Effect Permanent Organization.

A dispatch from Rochester, N. Y., says that announcement was made on Saturday that the United States Independent Telephone Company had that day completed its permanent organization at a meeting held in Rochester.

Thomas W. Finucane, the new president of the company, says that the company authorized its collateral trust mortgage of $25,000,000, and the underlying securities will comprise control of the Stromberg-Carlson Telephone Manufacturing Company, which manufactures a thousand telephones a day, and the New York Independent Company, which latter owns franchise rights claimed to be similar in character and scope to those of the Bell Company.

It is proposed to install a plant with an initial capacity of 225,000 telephones and an ultimate capacity of 750,000 telephones for New York City and the tributary districts which environ it.

The directors include Adolphus Busch, August Gehner and Breckinridge Jones, of St. Louis; George Eastman and Eugene Satterlee, of Rochester; Robert C. Hall, of Pittsburg; Joseph J. Heim and O. C. Snider, of Kansas City, and Hendrick S. Holden, of Syracuse.

Big Traction Deal.

A syndicate composed of Thomas Dolan, Randall Morgan and other men identified with the United Gas Improvement Company of Philadelphia, have bought of Tucker, Anthony & Co., of Boston, control of their extensive traction interests in Indiana and the Ohio Valley. The deal involves the payment of between $6,000,000 and $7,000,000 in cash, and carries control of the Indianapolis & Western and Indianapolis & Northwestern Traction Companies and a number of other important traction and electric lighting properties.

Lectures on Electricity.

The Board of Education of New York has provided for an interesting course of public lectures to be given by W. Wallace Ker on Tuesdays during the months of October, November and December, at the central branch of the Young Men's Christian Association, Fulton and Bond streets, Brooklyn. The course commenced on Tuesday evening and consists of ten lectures.

G. A. Rodenback, a graduate of the University of Wisconsin, has been appointed assistant in the department of electrical engineering at the Massachusetts Institute of Technology, Boston.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCT. 3, 1905.

Electric Railways and Appliances.

800,762. Trolley-Pole. Andrew L. Prentiss, Buffalo, N. Y. Filed Oct. 18, 1904.

800,816. Motor-Controller. Samuel S. Neu, New York City. Filed Oct. 10, 1904.

801,049. Railway Signaling System. Karl Scholz, Liebauthal, Austria-Hungary. Filed April 27, 1905.

801,165. Railway Signaling System. Herbert B. Taylor, East Orange, N. J., asssignor to the Advance Signal Company, Newark, N. J. Filed May 15. 1905.

Electric Lights and Appliances.

800,899. Incandescent Lamp. Frank M. Brooks, New York City. Filed Sept. 17, 1904.

800,993. Turn-down Incandescent Lamp. Samuel E. Doane, Cleveland, O., assignor to the National Electric Lamp Company, same place. Filed Nov. 16. 1904.

Electrical Machinery and Apparatus

800,823. Electrical Protective Apparatus. Charles A. Rolfe, Adrian, Mich., assignor, by mesne assignments, to the Rolfe Electric Company, Rochester, N. Y. Filed Feb. 13, 1903.

800,909. Controller-Regulator. Cyrus P. Ebersole. Keokuk, Ia., assignor to the Electrical Devices Company, same place. Filed July 23, 1902, Renewed May 5, 1904.

Telephones and Telephone Apparatus

800,675. Telephone-Receiver. Hermann G. Pape, New York City. Filed June 16, 1904.

800,747. Key for Telephone switchboards. Frederick H. Loveridge, Chicago, Ill., assignor to the Western Electric Company. Filed Dec. 13, 1902.

800,767. Telephone-Transmitter. Philip J. Spies and Rudoph C. Deuben, Chicago, Ill., assignor to said Spies and John M. Klein, a copartnership, same place. Filed Nov. 1, 1902.

800,855. Telephony. Isidor Kitsee, Philadelphia, Pa. Filed June 30, 1904.

800,907. Antiseptic Telephone-Mouthpiece. William B. Curtis, San Francisco, Cal. Filed April 18, 1905.

800,940. Telephone-Transmitter. Jerome Prince, Milford, Mass., assignor, by direct and mesne assignments, to the Prince Telephone Company. Filed Aug. 18, 1902.

801,034. Telephone-Receiver. William J. Murdock, Boston, Mass. Filed Jan. 5, 1905.

Miscellaneous.

800,619, Reversible Galvanic Battery. Charles B. Askew, Chicago, Ill. Filed Aug. 24, 1903.

800,638. Storage Battery. William Gardiner, Chicago, Ill., assignor, by mesne assignments, of one-hundred and fifty-one two-hundredths to the Universal Electric Storage Battery Company, same place. Filed June 11, 1904,

800,756. Protective Apparatus for Electrical Instruments. Frank R. McBerty, Evanston, Ill., assignor to the Western Electric Company. Filed Dec. 7, 1904.

800,834. Weather-Trap for Electric Wires. William H. Roney, Chicago, Ill. Filed Nov. 3, 1904.

800,854. Wireless Telegraphy. Isidor Kitee, Philadelphia, Pa. Filed Feb. 8, 1902.

800,873. Electrical Measuring Instrument. Edwin F. Northrup, Philadelphia, Pa., assignor to the Leeds & Northrup Company, same place. Filed Nov. 19, 1904.

800,885. Electric Cooking Apparatus. Gustav Teuber, Laasphe, Germany. Filed April 27, 1905.

800,902. System of Electrical Distribution. Rufus N. Chamberlain, Depew, N. Y., assignor to the Gould Storage Battery Company. Filed Jan. 12, 1904.

800,935. Electric-Wire Tower. La Verne W. Noyes, Chicago, Ill. Filed Feb. 11, 1904.

800,946. Polarized Electric Bell. Samuel C. Shaffner, Mobile, Ala. Filed July 15, 1903.

801,035, Electric Bell. William J. Murdock, Boston, Mass. Filed July 21, 1904.

801,132. Electrical Means for Detecting Contact Between Two Connecting Bodies. Mark Barr, Kensington, England, assignor to the Linotope Company, Limited, London, England. Filed May 31, 1901.

801,190. Electric Semaphore. Clayton E. Frederickson, Denver, Col., assignor of one-half to Jean F. Webb, same place. Filed Jan. 23, 1905.

THE TELEPHONE WORLD.

Takes Initial Step for New Telephone System.

Mr. J. J. Heim, on his return to Kansas City, Mo., from New York, where he paid a $100,000 filing bill on a $50,000,000 charter for the United States Telephone Company, gave out this statement: "This company is to be to the Independents what the American Telephone & Telegraph Company is to the Bell Companies. We have bought the Stromberg-Carlson Electric Company, which is to be to us what the Western Electric Company is to the Bell. We have bought the Independent companies in Rochester, Utica, Syracuse, and other important New York up-State points, and have secured a charter to allow us to invade the City of New York. There is only one company there now. We are going into that field to see what we can do with it as a competitor."

New Rules for Keystone Company.

By recent action of the Keystone Telephone Company's stockholders, the directors are deprived of the power to sell any of the corporation's real or personal property until a vote has been taken by the stockholders.

The meeting a special one, was held in Camden, N. J.

When Fiske & Robinson, of New York, recently obtained an important financial interest in the Keystone Company, and also got representation in the management, it was noticed that the New Jersey company owned most of the stock of the Philadelphia company and that under the present by-laws the board of directors could sell the property of the company without consulting the stockholders. It is believed that the action taken will put an end to the rumors that frequently occur that the conduits of the Keystone Company are to pass into the control of other concerns.

At the coming session of the South Carolina Legislature a bill will be introduced to require the Southern Bell Telephone Company to connect with all the small Independent lines in the State. The railroad commission is now investigating the telephone situation to find the cost of connecting lines, and the rates that would be equitable for long-distance connections.

Advices from Rochester, N. Y., state that the United States Independent Telephone Company will have control of a majority of the stock of the Rochester Telephone Company at 200 before the end of the year.

H. N. Mayberry, acting supposedly in the interests of the Home Telephone Company of Berkeley, Cal., has applied for a franchise there The trustees referred the petition to the street committee.

Articles of incorporation have been filed by the St. James Telephone Company of St. ames, Minn. Its capital stock is $25,000.

The Fowler Independent Telephone Company of Fowler, Cal., has been incorporated with a capital stock of $7,500.

A. B. Hunt, T. E. Parmalee and T. H. Polloch are after an Independent franchise in Omaha.

Independent and Bell Companies Chasing Prospective Subscribers.

Advices from Winona, Minn., say that the telephone war between the Winona (Independent), and Northwestern (Bell) Telephone Companies is on in full force. As a result of the recent annoucement of the Northwestern Company that it would raise rates to a level with those of the home company, the Winona Company has begun a vigorous canvass among the subscribers of the Northwestern Company. It is said that all the doctors of Winona except two have signed an agreement to cut out the Northwestern 'phone.

The Northwestern Company has placed a large force of solicitors in the field to hold its present subscribers and get additional ones. Both companies are using printers' ink liberally. The Northwestern Company has the largest list of city subscribers, but the home company has a complete county service among the farmers of the county and exclusive service in all city offices and schools and most of the county offices

Texas Clearing House for Independents.

The Texas Independent Telephone Clearing House Association has been organized at Dallas and application made to the Secretary of State for a charter.

The purpose of the organization is to facilitate the concentration of Independent telephone business in Texas. This will be a mutual benefit to several scores of telephone companies operating over the State.

The Fort Worth Telephone Company reports that its line into Dallas will be completed and ready for business on or about the first day of November.

Long distance connections have been recently completed from Fort Worth to Waxahachie, Waco, Houston, San Antonio and intervening points by this company.

At the annual meeting of the stockholders of the Frontier Telephone Company held in Buffalo, N. Y., the following directors were elected to serve for the ensuing year: William H. Andrews, Charles E. Austin, Martin Carey, Robert W. Chapin, William A. Douglas, Charles W. Goodyear, R. R. Hefford, Bert G. Hubbell,' Clark L. Iugham, Andrew Langdon, F. C. M. Lautz, H. H. Littell, E. C. Lufkin, H. H. Persons and George A. Plimpton.

It is stated that the party of Toledo, O., capitalists who some months ago promoted the Cuyahoga telephone deal, are negotiating for the control of the Independent Co-operative Telephone Company of Detroit, and that the property will likely pass into their hands.

The Bell Telephone Company is installing a conduit from Wilmington, Del., to Philadelphia, Pa., in which to place its trunk wires.

W. A. Wynne, of Raleigh, N. C., has secured a franchise to install and operate an Independent underground telephone system.

J. B. Pierce will act as general manager of the Independent Telephone Company of Syracuse, N. Y.

Bell Company Appointments.

The following appointments have been announced by the American Telephone & Telegraph Company:

H. S. Brooks, formerly district superintendent first district, to assist general superintendent, with headquarters in New York City.

Charles H. Fuller, formerly manager, Boston, Mass., district superintendent first district, vice Brooks; headquarters in New York City.

Henry McDonald, manager, Boston, Mass., vice Fuller.

J. L. Van Meter, superintendent of traffic at the head of the bureau of traffic; headquarters in New York City.

The Quincy Telephone Company of Quincy, Ill., which procured its franchise about a year ago, has sold its $500,000 issue of bonds to a St. Louis syndicate, which includes J. H. Murphy, a broker, and Charles Sutter, who recently assisted in consolidating the car concerns, representing a value of $50,000,000. The firm of Herman & Schatzman, brokers of Quincy, is understood to be financially engineering the project. The work of construction will begin immediately, and is expected to be completed by next April. Long distance connection will be made with St. Louis and Chicago, and about 5,000 telephones will be installed.

At the annual meeting of the Interstate Telephone & Telegraph Company of Aurora, Ill., the 17th regular quarterly dividend of 1 per cent. was declared on the entire capital stock of the Interstate Company. The report for the fiscal year ending June 30 also showed an increase of nearly $20,000 in the surplus over and above fixed charges, including interest and dividends, which was considered by the full board to be very satisfactory.

John L. Dunlop and J. M. Fetter, of Louisville, Ky., have been selected to do the underwriting in Kentucky for the United States Independent Telephone Company. The United States Company is a merger of a number of large telephone companies. It is capitalized at $50,000,000. The apportioning of the underwriting is in the hands of Breckenridge Jones, of the Mississippi Valley Trust Company of St. Louis.

Telephone Incorporations.

The Cream City Telephone & Telegraph Company, Jersey City, N. J.—to do a general telephone and telegraph business. Capital stock, $125,000. Incorporators: E. W. Dennison, Orange, N. J.; Norman Malcolm, Chicago, Ill., and William Lohman, New York.

The West Valley Telephone Company, West Valley, N. Y. Capital stock, $3,000. Incorporators: Christian Ehman, William H. Proctor, Fred E. Link and others, all of West Valley.

The Bath & Mitchellville Telephone Company, Bath, N. Y. Capital stock, $1,000. Incorporators: Clarence Myrtle, Thomas W. Robinson, Martin Armstrong, Leroy Keeler and Clarence G. Carey, all of Bath; Frank O. Rice, Wheeler, and Henry Faulkner, Urbana

GENERAL ELECTRICAL NEWS.

LIGHTING.

Athens, Ill.—The electric light plant in this city has been sold by Burnett & McMasters to Charles Carr, of Virden.

Burlington, Wis.—Taxpayers are making a determined fight against the establishment of a municipal electric lighting plant here and the issuance and sale of $12,000 bonds to pay for the same. Leonard J. Smith secured an injunction against the city, Mayor Mutter and City Clerk John T. Prasch, restraining them from proceeding in the matter. It is alleged that the recent vote was not legal because a two-thirds vote of the city did not ratify the plant.

Chatham, N. B.—This town has voted to apply to the Legislature for power to issue bonds for $35,000 for the purpose of erecting a new electric lighting plant.

Chicago, Ill.—John H. Radford is preparing plans for an addition to an electric light plant at 58th and Cottage Grove avenue to cost $200,000.—The Federal Electric Light Company's plant was lately destroyed by fire. The loss is $2,500.

Cicero, Ind.—The work of setting poles and stringing wires for an electric light plant is now in progress.

Depue, Ill.—This village is to have an electric lighting plant. A franchise for this purpose was granted at a recent meeting of the town board.

Ellwood City, Pa.—The Ellwood Electric Light Company has completed arrangements by which it will conduct electricity to Zelienople for lighting and power purposes.

Hastings, Neb.—The municipal electric light and power plant will have greatly enlarged capacity in the addition of a 400 hp. engine with generators, etc., costing between $15,000 and $20,000.

Holdenville, I. T.—The Charles De Watteville electric light and ice plant was lately destroyed by fire. The loss is estimated at $25,000.

Key West, Fla.—Ladd, Larkias & Jerguson have applied for a franchise to operate an electric light plant.

Kutztown, Pa.—This borough will soon have one of the finest electric light plants in the State. It will cost $15,000. Crude oil is to be used for fuel.

Lawrenceburg, Tenn.—This town will vote October 23 on the issuance of $25,000 of bonds for the installation of waterworks and an electric light plant. Address town clerk.

Milwaukee, Wis.—The resolution providing $60,000 for the purchase of a site for a municipal lighting plant has been signed by Mayor Rose.

Petoskey, Mich.—Petoskey proposes to obtain power for its electric light plant from the Boyne Falls Power Company, located at the falls of the River Boyne, 16 miles south of here.

Port Washington, Wis.—A municipal lighting plant and waterworks will be erected here.

Richmond, Va.—The joint sub-committee from the committees on finance, electricity and water, met lately and after carefully considering the report of Consulting Engineer E. W. Trafford on the proposed municipal light and power plant, adopted a resolution requesting the city attorney to prepare an ordinance for the issuance of $500,000 of 4 per cent. electric light plant bonds, and to draw all other ordinances necessary to put the scheme into operation and report back to the committee. The plant is to have a capacity of 2,000 hp., capable of being increased to 4,000. It is estimated, if none of the products of the plant are sold, it would save the city $37,000 annually in the cost of power and lights alone.

Tallapoosa, Ga.—This city will vote October 16 on the issuance of $10,000 of bonds for the construction of an electric light plant. George W. Sheppard, mayor.

Vinita, I. T.—The Vinita Electric Light, Ice & Power Company's plant was destroyed by fire, entailing a loss of $5,000.

Wisner, Neb.—The town authorities of this city have awarded the contract for an electric light plant to cost $5,000.

Woodward, Okla.—The Woodward Cotton Company has been granted a franchise by the council to furnish this city with electric lights and power for 20 years.

Wynnewood, I. T.—The city council has decided to call an election to vote on issuing bonds in the sum of $40,000 to build a system of waterworks and electric lights.

STREET RAILWAYS.

Brazil, Ind.—The surveyors for the Indianapolis & Ohio Valley Traction Company have begun the work of surveying through the city.

Champaign, Ill.—The Illinois Traction Company of this city has increased its capital stock from $5,500,000 to $7,500,000.

Connersville, Ind.—Work will begin on the traction line in this city at an early date.

Enid, Okla.—The city council has granted a street railway franchise to Daniel S. Roberts, of Baltimore. The system will cost at least a quarter of a million dollars.

Hamilton, Ill.—Survey work on the proposed trolley line between this city and Carthage was lately begun, and work on the line will commence at an early date.

Indianapolis, Ind.—The Louisville & Indianapolis Traction Company, the object of which is to construct and operate an electric line between Columbus and Jeffersonville, was recently incorporated with a capital of $10,000, by John R. Schindel and Samuel Adams.

Kalamazoo, Mich.—The electric line between this city and Grand Rapids seems to be an assured fact, work having already commenced on the road bed.

Lancaster, O.—There will be a new third rail line to Buckeye Lake next year. The Scioto Valley Company has surveyed and staked out the route with a branch line from Carroll to Millersport.

Madisonville, Ky.—Work will soon begin on the Madisonville traction line, which is to be built from this city to Nortonville, a distance of about 11 miles, making connection with the Illinois Central at that point. Mr. W. C. Morton says that deeds to all the right-of way have been secured, and just as soon as arrangements can be made for franchises through the streets of the small towns along the route work will be commenced.

McKeesport, Pa.—Work has been started by the West Penn Construction Company on the laying of tracks for the new trolley line from this city to Irwin.

Pittsburg, Pa.—A trolley line is to be built between Wilmerding and Wall in the near future. Subscriptions for stock in the company to the amount of $15,000 have already been received from Wilmerding people, and as only $25,000 is needed the road will soon be started.

Vincennes, Ind.—The officials of the Vincennes, West Baden & Louisville Traction Company have awarded the contract for the construction of the road and the erection of a power house to Louis Metesser, of New Orleans. The road will cost $3,000,000.

Willimantic, Conn.—The Willimantic Traction Company, which two years ago built a line 10 miles in length from this city to Baltic, has transferred the property to the Consolidated Railway Company, the holding company of the New York, New Haven & Hartford Railroad Company's trolley lines in Connecticut.

POWER PLANTS.

Bowling Green, O.—The county commissioners are about to give to the contractors the plans for a new power plant.

Colorado Springs, Col.—The Animas Power & Water Company of this city has been incorporated with a capital stock of $3,000,000 by L. E. Curtis, Henry Hime and O. B. Wilcox.

Duluth, Minn.—Contractors are now preparing proposals for the construction of the power distributing station for the Great Northern Power Company to be erected at Superior street and Fifteenth avenue.

Muskogee, I. T.—The Muskogee Commercial Club has received a proposition from G. W. Sargent, of Joplin, to build the Grand River power plant.

Whitney, N. C.—The Whitney Company, of which George L. Whitney, of Pittsburg, is president, has planned to erect an immense power plant here. The T. A. Gillespie Company of Pittsburg has the contract for the dam, canal and power house at about $2,000,000.

BIDS WANTED.

Fort Leavenworth, Kan.—Sealed proposals will be received until October 27 for the construction of five double sets of lieutenants' quarters, including plumbing, heating and electric wiring, at Fort Leavenworth. Envelopes to be indorsed "Proposals for Public Buildings," and addressed to Captain J. W. Normoyle, quartermaster.

Washington, D. C.—The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until October 17 for furnishing Eastern Navy Yards with the following supplies: Schedule 153, arc and desk lamps. outlet boxes, wire, wireless clusters, cabinet and distributing boards and miscellaneous electrical supplies; schedule 154, double conductor; schedule 155, incandescent lamps, carbons; schedule 157, electric deck hoists; schedule 158, copper wire, steel conduit and fittings, electrical supplies. Specifications and blank proposals can be obtained at the Navy Pay Office in New York, or upon application to the Bureau here.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅜@16⅝c.; Lake 16⅜@16⅝c.; casting, 16⅛@16⅜c.

It is reported that the Vanderbilts have acquired large holdings in the Cleveland Electric Company.

A director of the General Electric Company says that company is now doing the largest business in its history.

The Bullock Electric Manufacturing Company of Norwood, O., has increased its capital stock from $500,000 to $3,000,000.

The United Railways & Investment Company of San Francisco is paying 4 per cent. semi-annually on its preferred.

It is estimated that Boston now has an ownership in over 100,000 shares of Brooklyn Rapid Transit stock, or nearly one-quarter of the capital stock.

The full annual report of the City Railway Company of New York is expected to be ready for publication this week. It is said that the cash balance with reserve amounts to $1,700,000.

The United Electric Securities Company of Boston has declared a regular semi-annual dividend of $3.50 per share on the preferred stock, payable November 1 to stock of record October 21. Books do not close.

The Butte (Mont.) Electric & Power Company has declared the regular quarterly dividend of 1¼ per cent. on its preferred stock, payable November 1 to stockholders of record October 27. The dividend is made payable out of surplus earnings of 1904.

The annual meeting of the stockholders of the Third Avenue Railroad Company of New York to elect directors will be held November 6. Transfer books will close October 13 for this purpose and for the distribution of a quarterly rental on October 31 and will reopen November 7.

Mayor Dunne made it perfectly plain Saturday that he is opposed to the proposed ordinance of the Chicago City Railway Company both as to its form and spirit. He issued a message giving thirteen reasons why he considered it objectionable. Some of them are comparatively trivial.

A dispatch from Columbus, O., says it is officially stated there that the Widener-Elkins Syndicate of Philadelphia has purchased the Columbus, Buckeye Lake and Newark and the Columbus, Newark & Zanesville Electric roads. The purchase of the Appleyard interurban roads has not yet been completed.

W. B. McKinley, president and general manager of the Illinois Traction Company of Champaign, Ill., announces the authorization of an increase in capital from $5,500,000 to $7,500,000. The outstanding preferred stock now amounts to $2,420,000, and the amount of common stock now outstanding is $4,318,000.

The Great Eastern Telephone Company was incorporated at Albany on Monday with a capital of $1,000,000. The Great Eastern is an independent company, and is one of a system of three companies recently incorporated. It will operate in New York City only. The canvass for subscribers will begin in ten days or two weeks.

Articles of incorporation were filed in Hartford, Conn., on Friday by the Trolley Express Company of New Haven. The company is to carry merchandise over various trolley lines. The capitalization is $100,000. All the incorporators are officials of the Consolidated Street Railway Company.

EDITORIAL NOTES.

The London Electrical Exhibition.

The exhibition for which so much preparation has been made in recent months is now in full swing at the Olympia in London and it will remain open until October 21. From personal observation our London correspondent says that it is the largest electric lighting, power and heating exhibition that has been held in England, and it is now being visited not only by tens of thousands of the general public, whose interest in the up-to-date applications of electricity for commercial and domestic purposes it was intended primarily to enlist, but already there have been deputations of municipal electrical engineers and committees from all parts of the Kingdom. They have come up to London in order to become fully acquainted with the very latest illuminating and other novelties so that they may return the better able to appeal more convincingly to the general consumer and popularize their own supply system. Many more such visits have been arranged to take place before the show closes. There are a number of popular lectures being delivered by leading electrical experts during certain evenings, these arrangements having been made by the Institution of Electrical Engineers. Demonstrations of electric cooking and heating are also being given and money prizes are to be awarded for the best exhibits in these classes.

As there are 200 exhibitors it would be useless to indicate in detail the character of all the different exhibits. The Marconi Company has an interesting show of a wireless telegraph outfit as used on a Cunard liner. The General Post Office has a historical display of old telegraphic apparatus. The Electrical Volunteers Corps have lent their South African war equipment and some interesting mementoes. Electric disinfecting apparatus, ozonizers, the Dowsing light and heat cure appliances, including the "Solarium" home equipment, which has been already described by us—are a few of the novel lines, in addition to which of course everything employed in lighting and heating installations and a good deal of battery and generating plant are shown. Of heavy plant and railway apparatus there is not much of any importance—indeed such departments are hardly represented at all.

* * *

Why Steam Roads Adopt Electricity.

If it is believed by some that sentiment. or a desire to be very modern, has made the steam roads anxious to adopt electricity as part of their motive power, they are very much mistaken. The reason why the advisory and executive forces of steam roads have moved to utilize electricity as an adjunct to their present systems is simply because the loss of traffic they would otherwise sustain made it an imperative business measure.

The local traffic of all large steam roads within a short distance of New York City will be handled in the next two years by electric means. To become duly impressed with this view of the case it is only necessary to visit the neighborhood of the New York Central above 42d street, or 33d street and 9th avenue, where the gigantic station of the Pennsylvania Railroad will be constructed. Millions of dollars have been spent already in making excavations 75 feet deep over an area equal to 15 or 20 city blocks. The cost of this real estate with the houses standing was enormous, but they have all been torn down to make way for the new electrically equipped station, electrically lit tunnels and electrically operated cars. A sum, variously estimated to reach from $40,000,000 to $60,000,000, is to be spent by the above roads respectively, in order to retain and further develop their business as carriers of the public and transporters of freight.

An enumeration of a few instances outside of New York where electricity has been formally recognized as the most economical form of energy to use over long distances will prove interesting. The longest run of this kind is from Indianapolis, Ind., to Lima, O., by way of Dayton, an interstate line nearly 200 miles in length. The average speed is about 30 miles an hour and the fare 1½ cents a mile.

The next long run by electricity is made by the Lake Shore Electric, from Cleveland to Toledo, a distance of 120 miles. The run is made at an average rate of 25 miles an hour. As regards other lines of the interurban class, follow 22 belonging to the middle West, and about five in New York State, whose lengths vary from 30 to 80 miles. The lines at present in operation in New York State are as follows: The Hudson Valley, 60 miles long; the Rochester & Eastern Rapid, 44 miles long; the International (Buffalo to Olcott), 37 miles long; the Albany & Hudson, 37 miles long, and the Fonda, Johnstown & Gloversville, 33 miles long. It makes very little difference whether these roads are disparagingly entitled only trolley roads or not; they are and have been winning their way steadily to the front. This fact may be accepted as an axiom in the new world of railroad work, which has developed in the last ten years, that wherever an electric road parallels a steam road the steam road loses money. It is just as good a passenger and freight carrier; it can run just as quickly, and it can stop at a variety of points convenient to those patronizing the road without losing much on its time schedule. This fact, hammered home, by the experience and receipts of electric roads, has been duly digested by the better class of thinkers of the steam traction systems. They have felt compelled to save themselves from the loss of a vast amount of transient and local business in the near neighborhood of large cities by adopting the weapons of their competitors. The New York Central reaches out 35 miles beyond New York City, the Pennsylvania will reach out over 50 miles from New York City—with its new electric passenger and freight service.

This last lesson in railroading was not taught by the older pupil, but by the newer. Steam roads, it seems, to save themselves are rapidly becoming electric roads.

* * *

Electricity in the Sahara Desert.

The empire of that celebrated Parisian boulevarder, who proclaimed himself King of the Sahara, is about to fall under the block of modern science. Its isolation, its mystery and its farawayness are to be things of the past. The project, once deemed unnecessary for an unnecessary ocean of sandy waste, will be carried out in all its completeness. It is going to be possible to wire messages from the interior, or coast of Algiers, to the very heart of the Sahara Desert. The telegraph line will stretch from the Mediterranean to Timbuctoo. It may not be known to the laity that a line from the Tuat Oases to the northern coast has been in operation for some time. The Tuat Oases, it may be said, were one of the stopping places of those roving pirates whose outrages upon caravans were features of history from time immemorial. "The French are just now selecting the route to the south of the Ahaggar Mountains, where the bandit Tuaregs live when at home. The Tuaregs are now quietly tending their herds, for the new masters of the Sahara have made the plunder of caravans an unprofitable profession." According to reports, the telegraph will reach southwest to the region represented by the city of Timbuctoo at which the pole line will end. The French believe the line work, the pole setting and the testing will be completed before the winter months are on. Timbuctoo is a spot where no white man dared to appear in recent times. To live in this city, an Arabic tongue, a devotion to Islam and a stained skin were the possible preservatives of life. The glacial approach of civilization has made its presence felt, in the form of its best advance guard, the telegraph. Tourists may soon be sightseeing in a region once deemed almost inaccessible and doubly dangerous through the science and enterprise of distant Europe.

The strike of the electrical workers in Berlin, Germany, is ended. A cable dispatch says that at a conference on Saturday the delegates of the workingmen voted to accept the associated companies' original offer of 5 per cent. increase in wages. The result is a complete victory for the employers. The decision of the hardware manufacturers to lock out their 20,000 workmen unless the electrical strikers returned to work was the prevailing reason for the strikers' acceptance of the terms offered to them.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Secretary H. E. Bradley informs us that the Pennsylvania State Independent Telephone Association will hold its annual convention at Pittsburg November 9 and 10.

New York City is building an incinerator for its first municipal light station, which will soon be completed. The fuel to be used will be the waste paper and rubbish gathered by the street cleaning department.

The Consolidated Railway Company, the electric holding company of the New Haven Railroad, now has 26 lines, of which 15 are constituent companies, five are leased lines and six are controlled lines. The total investments of all kinds in the Consolidated Company are $37,199,220. Including recent purchases and extensions the total mileage of the company is now 588.

The European rights for the De Forest wireless telegraph patents have been sold to a syndicate of prominent Englishmen. The capitalization of the English company is $600,000.

The Bell Telephone Company is "playing politics" in New York to keep out its independent rival. The city's Finance Department engineer thinks a franchise for the independents is worth $7,750,000—a very unjust exaction. The independent company, however, is determined to fight for its rights.

The part which electrical development has played in the growth of cities in New York State in the last five years is shown by the fact that Schenectady—the headquarters of the General Electric Company—has made a gain of 84.2 per cent. in population since 1900.

In a recent interview with a newspaper correspondent Mr. Edison said that after working out his new electric motor storage battery idea he made 14,000 cells and sent them all over the country for trial. About the result he says: "I have got back all those cells, have sifted the matter down, and I am now perfecting the model cells. By next spring I will have 400 new cells made. We will have big works to turn them out. The new cell will not cost any more than the painting and the tires of a wagon. I don't think that the cost of operation will be quite as great as the cost of horses."

LOCATION OF SMALL SWITCHES AND FUSES.

BY W. H. WAKEMAN.

In the plant which I have charge of at the present time the boiler room is lighted better than the engine room, so far as natural light is concerned, therefore electric lights are needed all day in a part of the latter, but are not required in the former. In order to save the trouble of shutting off each lamp separately, all that are in the boiler room and those in the lighter portion of the engine room were put on one circuit and a snap switch installed at a convenient point, so that a step ladder is no longer required when it is desired to shut off some of the lamps.

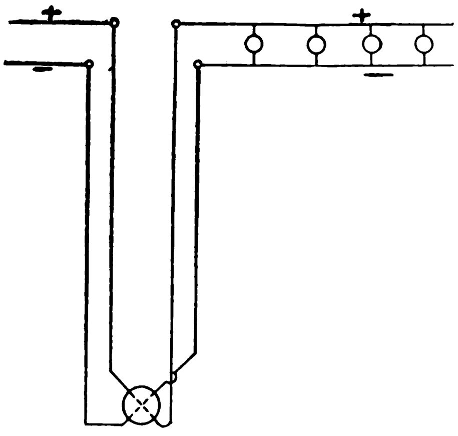

FIG. 1.

Fig. 1 illustrates this, showing how the wires were brought from the ceiling downward to a point about 5 feet from the floor, where the snap switch can be reached easily.

It will be noted that both wires are brought down, and a four point switch used, thus completely severing all connection when it is turned off. Some engineers think this unnecessary, and I have been told that my plan calls for unnecessary labor, as the plan illustrated in Fig. 2 is "just as good," and requires less labor."

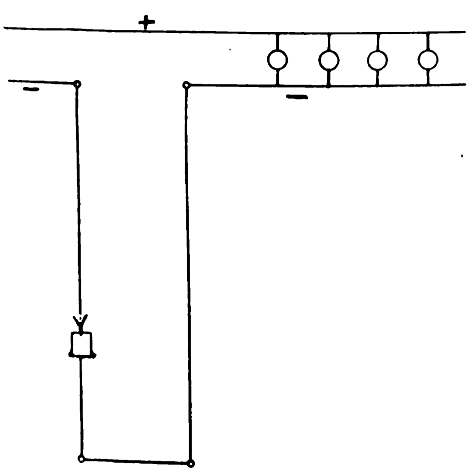

FIG. 2.

Patent medicine proprietors and others warn us against the use of spurious substitutes which are "just as good" in the estimation of others. This idea may be applied to electrical work with profit, provided it is done in an intelligent way, for where a certain plan for wiring rooms has proved sufficient, it may not be wise to change it.

This calls for a two point switch located in the negative line, for when it is thrown out the circuit is broken, consequently all lamps on that line go out. The same effect will be secured if the switch is placed in the positive line, for it breaks the circuit just the same. As a rule the engineer of a plant does not know which wire is positive, because there are so very few cases in which it is necessary to know this, except where arc lamps are used, consequently it is well to remember that a single point lever switch, or a two point snap switch may be located in either the positive or the negative lines, as it will then shut off all lamps on that line.

There are some reasons, however, why it is better to sever the connection in both wires, as the following incidents plainly show.

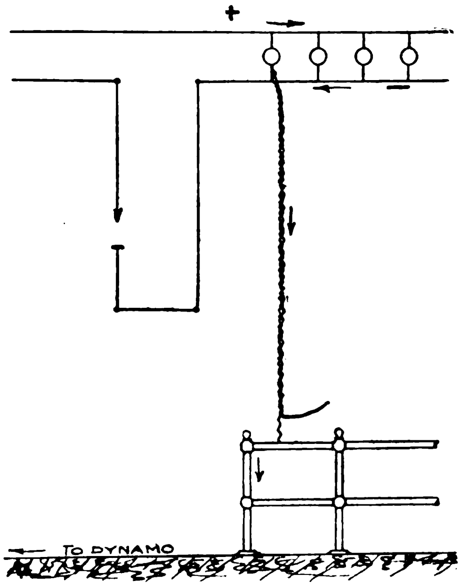

FIG. 3.

Fig. 3 illustrates a switch in the negative wire of a circuit, and a lamp cord hanging down from a rosette in the usual way. The negative wire of this lamp cord came in contact with a brass railing as shown, causing all lamps to light, much to the engineer's surprise. Current came over the positive wire, passed through the lamps in the usual way, returned as shown by the arrow, went down to the railing and from thence traveled through earth to the dynamo.

In this case there are but three lamps shown beyond the rosette carrying the lamp cord, as these are enough to show the principle involved. No harm was done in this case because all current coming to the railing had to pass through the lamps, and they acted as a check to the rapid flow of current.

Fig. 4 illustrates the same plant, but here the positive wire is in contact with the railing, hence a much larger quantity of electricity passed, because there was nothing to hinder it, consequently a hole was burned in the heavy brass pipe, which disfigured it, but a valuable lesson was learned, as the experience showed that a dangerous quantity of electricity may pass over a circuit of which the earth forms a part, when the negative wire of the metallic circuit is disconnected.

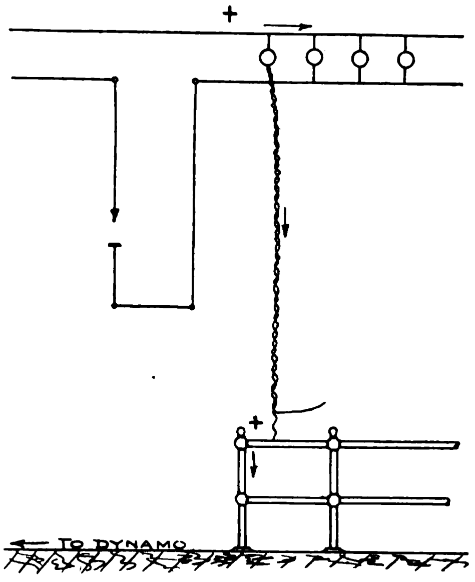

FIG. 4.

Fig. 5 illustrates an accident somewhat similar to the foregoing, although it resulted from a different cause. Potential between the two main wires was carried at 550 volts, and as it was desirable to use 110 volt lamps, five of them were connected in series. The lower lamp was used on a long cord to provide light on the top of a battery of boilers whenever it was required for repair work, etc. While screwing up a nut the engineer caught this cord between his wrench and a steam pipe, which quickly burned off

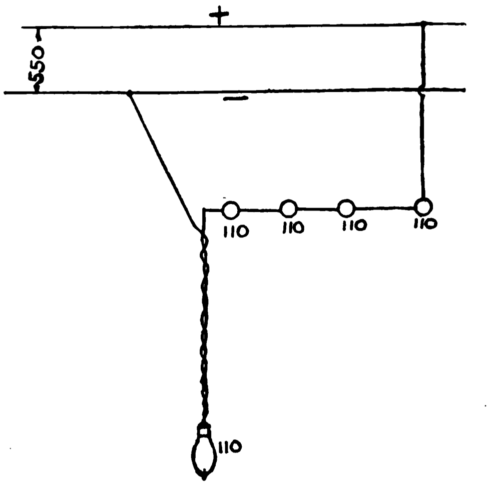

FIG. 5.

the insulation. Evidently this brought the negative wire in contact with the iron pipe, and as a heavy current was passing at that instant enough of it was diverted from its natural course to "burn a hole" in the pipe, using a common expression, or in other words to melt a small piece of the metal.

My reason for believing that it came from the negative line is that the current coming through five lamps is not enough to accomplish the result mentioned, but other connections at other points were sufficient to transmit the required amount from the positive to the negative wire.

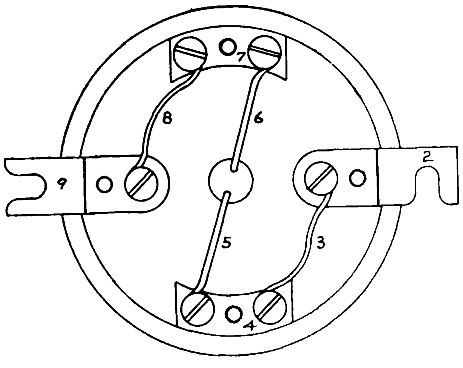

FIG. 6.

Fig. 6 represents a rosette for connection between the positive and negative wires of an ordinary circuit. It may be explained as follows. Connection may be made with the positive wire 2 causing current to pass over the fuse 3 to the cleat 4 to which the positive wire of the lamp cord 5 is connected. As current goes down 5 and returns over 6 it passes to the cleat 7 over the fuse 8 and the connection 9 to the negative wire of the line.

This is a safe form of connection, because it is impossible to draw more current by a short circuit on the lamp cord, than either of these fuses will carry, and as they should always be very light, one or both of them will melt before the main fuse for that branch line fails. It is possible to melt both of them, provided the short circuit is made between the two wires composing the lamp cord, but if it is made by connecting one wire to a brass rail, or some other piece of metal, only one fuse will melt, as due consideration of Figs. 3 and 4 plainly show.

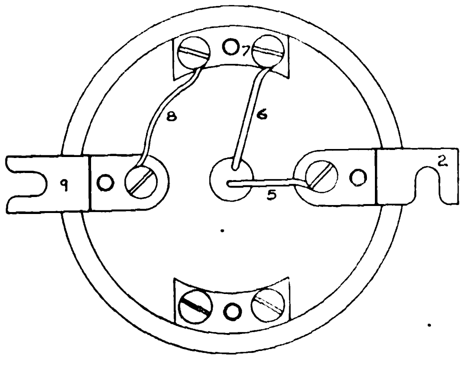

FIG. 7

Fig. 7 illustrates a rosette containing but one fuse. Current may come from the positive wire over the connection 2, and as there is no fuse 3 to connect it to the cleat 4, it goes directly to the positive wire of lamp cord 5, and after passing the lamp it returns over the negative wire 6, goes to the cleat 7 and the fuse 8 which carries it to the connection 9, and thence to the negative wire of the branch circuit.

To illustrate the possible mischief due to such a connection it is only necessary to mention the system installed in one building forming part of my present plant. It is a three-wire system to junction boxes on each floor, and from these boxes two wire branch circuits are carried wherever lights are wanted. Suppose there are eight lamps connected to a branch circuit, and the positive wire is connected without a fuse as at 5, Fig. 7. The positive wire of the lamp cord is brought into contact with something forming a good connection to earth.

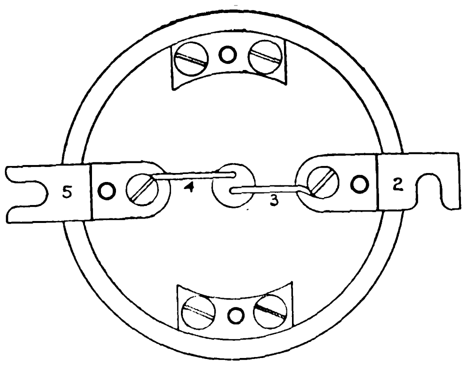

FIG. 8.

Where the branch line leaves the main line there is a 10 ampere fuse plug on each wire connection, consequently the short circuit mentioned melts the 10 ampere fuse and puts out eight lamps. Searching for the defective connection shows that all fuses in eight rosettes are in good order, therefore the cause of trouble remains a mystery. Replacing the melted fuse plug restores the branch line to usefulness, but if this rosette had contained two fuses like Fig. 6, only one lamp would have gone out, thus locating the trouble at once.

Fig. 8 illustrates a rosette without fuses, thus causing current to come in over the positive connection 2, pass directly down the lamp cord wire 3 past the lamp, coming up 4 and going over 5 to the negative wire. It is legal to make this kind of connection, as the law no longer requires fuses for each lamp, but it causes all lamps on a given branch circuit to fail, as the result of a short circuit, when otherwise only one lamp would be affected.

Perhaps some reader will claim that short circuits of this kind are not liable to occur, but more than 10 years' service as engineer in an educational institution, has taught me that hundreds of mischief-loving boys can invent many things that are not on the programme to spoil the best laid plans. Furthermore ignorant workmen in a mill or factory seem to have a special gift for inventing plans for short circuits, breaking wires, etc., thus causing the engineer in charge unnecessary work and worry.

UP-TO-DATE ELECTRICAL POWER DISTRIBUTION.*

BY R. L. GAMLEN.

It is now about 28 years since electricity was first generated commercially. With Mr. J. W. Swan's discovery of the carbon filament the incandescent lamp offered at once a solution of the problem of internal lighting. Not long afterwards the first early attempts were made at electric traction.

Developments soon came which not only made the working for lighting better, but also made the supply of power a possibility.

The immense value of a power load became at once apparent to supply engineers, as here was a chance of increasing their working hours of utility, and they at once started to put their works in order so as to profit as far as possible by this new source of revenue and to cater for it to the best of their ability. They have succeeded to a great extent, but the old system had its limits, and great power companies have sprung up to deal with the question. Not as a patchwork of old methods, but starting *de novo*, and on lines designed for the particular work, with none of the old unnecessary drawbacks, but with all experience at their back.

A demand has come for: (1) Electricity to be supplied more cheaply than it can be made by individuals; (2) a supply so certain that, but for a veritable "act of God," no cessation can occur; and (3) a supply so regular that the angular velocity of the motors is more constant than the best results before obtained.

In the records of electricity concerns a capital of $500 per kw. of plant is no uncommon figure; but a quarter of this figure should be obtained by a power company. The factors controlling the choice of plant are: Absolute immunity from breakdown, perfect regulation, small fuel consumption, ease of working, and consequently a low wages bill.

---

*Abstract of paper read before the British Institution of Mining Engineers.

The power companies have in nearly all cases laid out their schemes on somewhat similar lines. Three-phase distribution has been adopted, at a pressure of about 10,000 volts. The current has been generated at high pressure, generally by means of turbines running with high vacuum and high superheat. The water-tube boiler has been universally adopted, and one or another form of mechanical stoker used.

In the case of Lancashire, the first station has been placed between the River Irwell and the railway, upon the far side of which is a coal mine from which supplies can be obtained. The site is convenient, inasmuch as there is an ample water supply for condensing purposes; the railway being situated above the boiler house, the coal is conveyed by gravity into the bunkers, and thence it is fed on to chain-grate stokers, operated by electric motors. The first boiler house is divided into two banks of three boilers. The two banks are each capable of evaporating 60,000 pounds of water per hour. The boilers feed on to one common ring of pipes, and the turbines are fed from the same, so that two turbines are fed from one bank. One bank of boilers then, with its chimney and two turbines, constitutes 1 unit. It is proposed to make extensions in like manner, except that instead of one bank of boilers feeding two turbines, each bank will feed one machine of larger capacity. The water-tube boiler is used on account of the very great steaming capacity for a given floor space, and of its great powers of responding to forcing. It is, of course, highly important when dealing with large generators to arrange that sufficient boiler capacity can be available without the steam having to travel through vast lengths of main. By placing the boilers at right angles to the turbines, very satisfactory arrangements can be arrived at.

The turbines revolving at 1,000 r.p.m. look, of course, exceedingly small for the amount of work they do; indeed, the amount of power that can be obtained on a certain floor space by their means seems nearly incredible to the engineer who has been accustomed to work with the older slow-speed engines. The turbine lends itself particularly well for condensing; in the case of the Curtis turbine there is no exhaust pipe, the condenser being coupled direct to the engine. This can be done in two ways: either by placing the condenser side by side with the turbine, or underneath, either arrangement being very compact and convenient. In Lancashire the air-pump is placed beyond the condenser, so that the three form really one plant. The result is that an engine room only 96 feet long and 32 feet wide, is needed to house four sets of 2,000 kw. each, or 8,000 kw. in all; whereas in nearly all previous cases as large a building has been necessary for an engine of 800 hp. and less. When the extensions take place, this ratio of plant and buildings will diminish again, as the diameter of the 5,000 kw. set is comparatively little larger than that of the 2,000 kw. plant. In the case of the Curtis combination, the dynamo is placed on the same spindle as the driving buckets and vertically above them. Owing to the high speed of rotation the electrical generator is of very small proportions, the diameter being only some 7 feet; whereas an ordinary direct-coupled set, at about 150 r.p.m., would be somewhere about 25 to 30 feet high, and, of course, much more expensive.

The three-phase current generated at the high pressure of 10,000 volts is carried to the switchboards. A great deal depends upon the design of this section. The operation must be easy, there must be no danger from fire, and the whole must be safe. The system known as remote control has been employed almost universally. The danger of switchboard trouble is overcome; no mains of large power are on the operating board, so that there is nothing to fire; and even if any little accident did happen it would not damage the main cables, as they are not near, and the supply would not suffer. Here, again, the simplicity is such that one man can look after and control what would before have needed perhaps five or six men.

By being able to spread over large areas, great varieties of load can be catered for, and these different requirements balance out one with another, giving a very constant load at the station. It is likely that the number of units produced by a power company when attaining to moderate size for each kilowatt demanded should reach 2½ times that of the ordinary town supply—that is, the load factor of an ordinary combined lighting and power supply will be high at 18 per cent., while that of the power company should reach 45 per cent., and this greatly reduces all the annual capital charges.

There is great prejudice in this country against the use of overhead mains, but this is gradually being overcome, and already great advances are being made. In the original scheme, the whole of the Lancashire mains were intended to run underground; already it has been arranged that some 10 miles of route shall be overhead. By this means, expensive insulation is saved, and also the excavation and reinstatement of the roads, greatly reducing the cost of the transmission system. Further reduction is obtained also, as often the cross-country overhead route is much shorter than if the routes had to be followed. The main roads are laid in duplicate, and are planned to go through the most likely districts for supply.

Arrangements are made with the various local authorities for the supply in their areas. In some cases, the current is sold to the authorities, and they distribute to the small consumers at low pressure; in other cases, the company act more or less as agents for them and look after the distribution. In all cases, large power users are served direct from the high-tension mains. In most cases the current used is three-phase, as this is most suitable for almost all purposes; the reduction apparatus in this case has no moving parts and requires no attendance, so that even in this extra stage to that needed by the ordinary supply concern no extra expense is incurred.

The following points indicate the general scheme of the lay-out of the power company, and show where the differences occur between it and the ordinary town supply: (1) The power company chooses its site near the fuel and the water; (2) the power company spreads out over a large area, and caters for a large long hours' load, consequently it can start on large lines with large units of plant, the capital cost of plant per horse-power diminishing as the size increases; (3) the load factor of the power company should reach 45 per cent., and (4) all the working expenses of the power company per unit are extremely small on account of the size and convenience of the units. On the other hand: (1) The town supply is located by the area of supply, and it seldom can be placed near water, and hardly ever near a coal-pit; (2) the town supply has a constricted area, and can only work in small units, and small units are more costly per horse power than large ones; (3) a good mixed town supply can hardly ever have a better load factor than 18 per cent.; and (4) the wages bill of a town supply is generally a large factor of the total costs.

The preceding recited points show that power companies hope to be able to supply electricity far more cheaply than town undertakings, and the future will show whether their ideas are based on fact or on fiction.

LIGHT, HEAT AND POWER PRINCIPLES.—IV.

BY NEWTON HARRISON, E. E.

Light and Lamp Efficiencies.—The amount of light obtainable from a horse power or kilowatt of electrical energy is not limited by theory, as it is by practice. The ordinary 16 candle power lamp, is only a stepping stone to better forms of illumination, as far as power consumption is concerned. It is not to be forgotten that the incandescent lamp, which now takes from 3 to 4 watts per candle power, has been built to take only 1 watt per cp., though under such circumstances its durability becomes a matter of great question. The following table illustrates the amount of light produced by 1 horse power and 1 kilowatt of electricity by lamps consuming various wattages per candle power:

TABLE OF LIGHT PER POWER UNIT.

Watts per candle power in lamp.	Candle power per kilowatt.	Candle power per horse power.
5	200.0	149.2
4.5	222.2	166.0
4.0	250.0	186.5
3.5	285.7	213.0
3.0	333.33	248.6
2.5	400.00	294.4
2.0	500.00	373.0
1.5	666.66	497.3
1.0	1,000.00	746.0
.5	2,000.00	1,492.0

Short Life with High Efficiency.—The carbon will not last, if pushed to too great a temperature in giving light. The use of only 1 watt per candle power in lamp construction represents so great a risk that no guarantees of any description are given with such lamps by the factory. Only lamps using rare oxide filaments are expected to have so great an efficiency, and still possess durability. The economic side of the question is best presented by means of another table, in which the number of lamps rated at 16 candle power, which might be used per horse power or kilowatt on this basis are given:

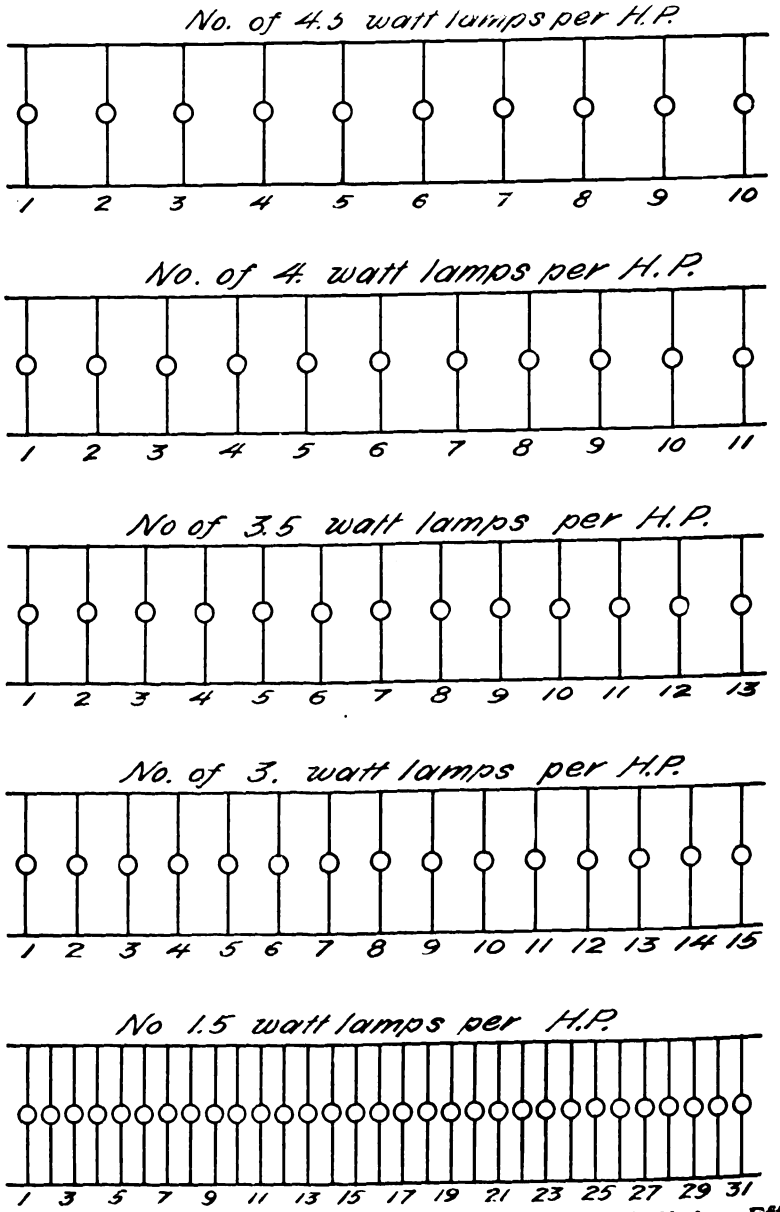
Number of 16 cp. lamps per horse power.	Number of 16 cp. lamps per kilowatt.	Watts per candle power.
9.32	12.50	5.0
*10.40	14.00	4.5
*11.60	15.62	4.0
*13.30	17.8	3.5
*15.50	20.83	3.0
18.40	25.00	2.5
23.31	31.25	2.0
31.00	42.00	1.5
47.00	62.50	1.0
93.25	125.00	.5

The figures marked with a star are those which lie within the range of general electric light practice; representing the use of lamps, whose watt consumption per candle power varies from 3 to 4.5. Along the line of figures giving 1.5 watts per candle power may be found, under the heading of lamps per horse power and per kilowatt respectively: 31 and 42. A lamp which in electric light practice takes only 1.5 watts per candle power will be the means of increasing the available number of 16 candle power lamps of the regular type, from 15 or 20 to 30 or 40. It is not a difficult matter to imagine the advantages of this to a station whose capacity is tested to the limit. A station, for instance, in which the generators can only supply 10,000 16 cp. lamps under ordinary conditions; but which actually has its capacity increased by the use of more efficient lamps to the extent of being able to double its lighting as far as the number of lamps are concerned. From the economic standpoint already referred to, the station income is by such means so greatly increased that the engineering side of it becomes rapidly transformed into a financial advantage of large dimensions. To further accentuate the benefits arising through the use of efficient lamps, the case of a 1,000 light station is given, in which the increase in lamps is tabulated as the watts per candle power are diminished:

CAPACITY OF A 1,000 16-CP. STATION UNDER DIFFERENT CONDITIONS.

Supplying power to	Lamps.
3.5 watt lamps.	1,000
3.0 " "	1,166
2.5 " "	1,400
2.0 " "	1,750
1.5 " "	2,333
1.0 " "	3,500

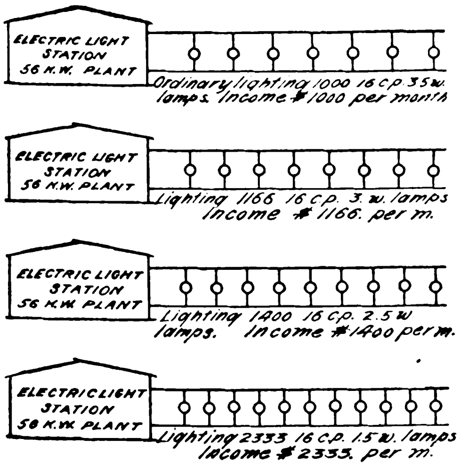
The reason why so many different efforts have been made to produce a lamp so much more efficient than the one in general use is largely found in the above figures. A station supplying power to light 1,000 lamps could, by the introduction of a lamp whose efficiency is represented by any of the figures given, increase its lighting capacity 50, 100, 200 or 300 per cent.



Increasing Capacity of 1 HP. to Give Light with Lamps of Higher Efficiency.

Another Feature of Higher Lamp Efficiency.—The cost of a lamp, whose renewal is more frequent because of its higher efficiency, also calls for consideration. If a higher efficiency lamp burns only half the time of a lower efficiency lamp, but during that time takes only half the power of the second lamp, the question arising is this : In comparing the value of the power saved with the value of the lamp, is there an advantage or a loss? For instance, if a lamp costs one dollar, but it saves one dollar's worth of electricity, is there any gain in the experiment? The answer is best given in the form which takes into consideration the fact that the station has been able to double its capacity as a source of electricity for lighting. The earning power of the plant has been doubled because it can double its customers with the additional expense of only doubling its lighting facilities outside. If the cost of the lamp is prohibitive, because its replacing is too expensive, then the advantage of a higher efficiency is lost.

The advantages are best set forth, however, in a table showing the increase in the income of a plant on the suppositious basis of about $1 a month per 16 cp. lamp:



ELECTRIC LIGHT STATION 56 K.W. PLANT
Ordinary lighting 1000 16 c.p. 3.5 w. lamps. Income $1000 per month
ELECTRIC LIGHT STATION 56 K.W. PLANT
Lighting 1166 16 c.p. 3. w. lamps Income $1166. per m.
ELECTRIC LIGHT STATION 56 K.W. PLANT
Lighting 1400 16 c.p. 2.5 w lamps. Income $1400 per m.
ELECTRIC LIGHT STATION 56 K.W. PLANT
Lighting 2333 16 c.p. 1.5 w. lamps Income $2333. per m.

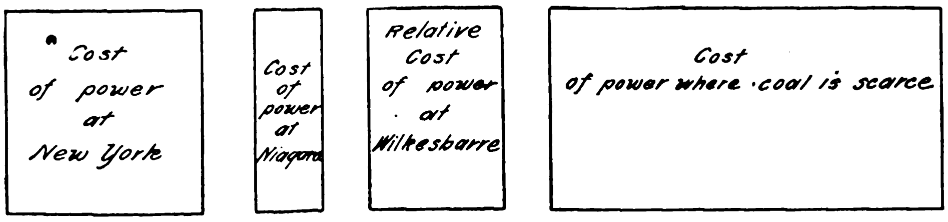
Increased Capacity of a Plant with Low Watt Lamps.

Increase in income of a 1,000 3.5-watt lamp plant. Dollars increase per month.	Number of lamps of higher efficiencies.
$1,000	1,000 3.5-watt lamp.
1,166	1,166 3.0 ‘‘ ‘‘
1,400	1,400 2.5 ‘‘ ‘‘
1,750	1,750 2.0 ‘‘ ‘‘
2,333	2,333 1.5 ‘‘ ‘‘
3,500	3,500 1.0 ‘‘ ‘‘

Any form of engineering or finance that can make a given condition become more productive is unquestionably superior to that originally prevailing. In the application of electricity to certain purposes, like electric light or power, a guidance in doing things is often best obtained by reference to the ultimate purpose of the enterprise. In electric lighting particularly the two important features which present themselves are, first, the cost of the power, and second, the amount of light from a given amount of power.

Cost of Power.—The cost of fuel is only one part of the cost of power. The more expensive the machine in which fuel is burnt the more expensive is the act of consuming it. But the expensiveness of a machine is always proportional to its economy, in such fields of engineering as relate to electric light and power work. In other words, the manufacturers of very economical devices believe that the saving due to the devices exploited should be partly divided. For this reason highly economical forms of apparatus due to special inventive talent, that necessitated costly experimenting to produce, are also expensive. A high grade boiler, engine or generator calls for an investment larger than one of inferior grade. In electric lighting the best of machinery is generally employed, because the saving qualities of certain classes of apparatus are such that the annual gain by their use far outweighs the additional expenditure necessary by their purchase. Burning coal in a high grade boiler means the combustion of fuel in a device, whose original cost is great enough to make it and the other elements of the station, constitute a heavy investment; the interest which must be earned to make this investment a financial success is earned by the coal when its energy is transformed into heat, steam power, electricity and electric light and power. The cost of power depends, therefore, upon the two items—of cost of fuel, and extent of the investment for machinery, real estate, conductors, lamps, etc. An illustration of this fact can be drawn from the following table covering various degrees of investment:

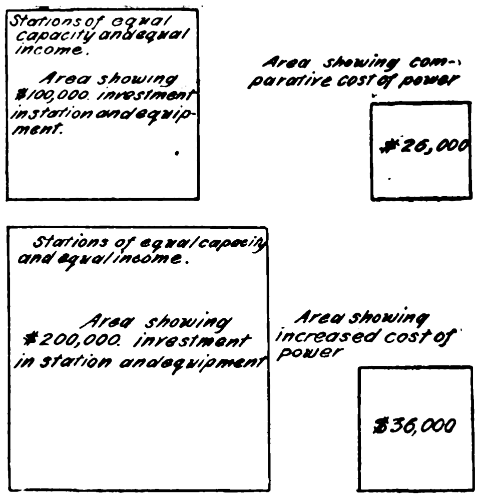
Cost of fuel per annum.	Cost of station.	Interest on investment at 6 per cent.	Cost of fuel and interest.
$10,000	$100,000	$6,000	$16,000
‘‘	200,000	12,000	22,000
20,000	300,000	18,000	38,000
‘‘	400,000	24,000	44,000
30,000	500,000	30,000	60,000
‘‘	600,000	36,000	66,000
50,000	700,000	42,000	92,000
‘‘	800,000	48,000	98,000
100,000	900,000	54,000	154,000
‘‘	1,000,000	60,000	160,000



Cost of power at New York
Cost of power at Niagara
Relative Cost of power at Wilkesbarre
Cost of power where coal is scarce

Relative Effects of Locality Upon Cost of Power.

The table given is not statistical, neither is it based upon calculations derived from data relating to electric light practice. It simply illustrates the idea of the increasing cost of power, though the fuel does not increase in price per ton, with the increased heaviness of the investment for machinery, real estate, conductors, etc. If, for instance, the cost of one station is $100,000, as compared with the cost of another station of $200,000, and both produce the same amount of power, require the same number of employes and have the same number of customers for light and power—then with equal efficiencies, the power of one station costs much more than the power of the other to produce. This can be illustrated in the following estimate, in which $10,000 worth of coal is supposed to be burnt up in each per annum :



Stations of equal capacity and equal income.
Area showing $100,000. investment in station and equipment.
Area showing comparative cost of power
$26,000
Stations of equal capacity and equal income.
Area showing $200,000. investment in station and equipment
Area showing increased cost of power
$36,000

How a Heavy Investment Increases the Cost of Power Relatively per Unit.

Investment of $100,000.		Investment of $200,000.	
Interest..	$6,000	Interest..	$12,000
Fuel.....	10,000	Fuel......	10,000
Labor....	10,000	Labor....	10,000
Total...	$26,000	Total....	$32,000

As all the expenditure each year as well as each month, week and day, is for the purpose of producing light and power at the other end, it is quite evident that the spending of large sums in the installation and equipment will mean a greater cost for power, unless it is recognized that the best of judgment was used in making the expenditures, and that they were made for indispensable elements of the plant.

Cost of Power in Various Localities.—Localities have a great influence upon the cost of power per horse or per kilowatt. At Niagara Falls, neither the ground nor the power itself is a source of heavy expense. In New York City, the same amount of power would mean large investments for costly real estate, for coal and for conduits for the subterranean conductors. In the neighborhood of coal mines, where fuel is cheaper because of the saving in freight, power would be cheaper. The cost of power is in many respects largely proportional to the investment required to produce it.

SOME RECENT DEVELOPMENTS IN SUBMARINE SIGNALING.*

BY ALFRED GRADENWITZ.

Sending sound signals through the air has long been the only means of insuring the safety of ships in fogs, but the limited range of such signals, and the extreme variability in the sound transmission through the atmospheric air, due to fluctuations in the density and temperature of the medium, as well as to the disturbing effects of wind and the sound-damping influence of snow, considerably reduce the efficiency of this method. There is further the liability of the signal to be disturbed by echoes, and the impossibility of accurately locating the origin of a sound reaching the ear. The majority of the terrible disasters to ships which occur every year may be said to be due to the vessels losing their course in the fog.

Now, as water is not subject to the same variable influences as air, while it is a more efficient sound conductor than the latter, submarine signals must obviously be far more reliable than those sent through the air. Sea water has practically the same density at any depth, and the velocity of sound in this medium is four times as great as in air; whereas in the latter sound travels about 1,100 feet a second, the rate in water is 4,712 feet, or almost one mile a second. On the other hand, the velocity of the tidal currents in the ocean is considerably less than the speed of the wind above its surface, which, in the case of storms, will frequently reach 30 miles per hour.

Furthermore, there is below the surface of the sea practically no noise liable to interfere with the sound signals, experience having shown these to be heard and located equally well in the most violent storm as in perfectly calm weather.

A highly important invention, enabling submarine signals to be used with a view to increasing the safety of ships, was made six years ago by Arthur J. Mundy, of Boston. The idea of the "submarine telephone," as his apparatus may be termed, was impressed upon him by the loud report of a stone falling into the water while his head was beneath the surface. Not being a practical inventor, he induced the late Prof. Elisha Gray to co-operate with him in developing the idea into a practical system. On account of his discoveries in telephony Prof. Gray was exceptionally competent for carrying out this difficult work. He made the sounds convert themselves into electrical impulses by relays, and when this problem was solved the working out of practical details proved comparatively easy. Shortly before his death Prof. Gray was able to make a test before a company of scientists and prominent business men, whose report was highly in favor of his system. Among these men were Prof. Elihu Thomson and Henry M. Whitney. With the assistance of eminent engineers and scientists, Mr. Mundy succeeded, after Prof. Gray's death, in carrying the invention through to its present perfect condition.

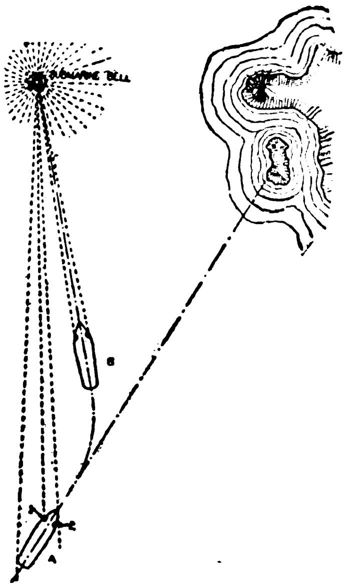


Fig. 1.

The apparatus, which is doubtless destined to prove a most valuable aid to mariners in their struggle against fog, is simple in construction, and can be fitted into vessels without any great expense and without any damage to the shell. It comprises two essential parts, viz., a special type of immersed bell, serving to produce the sound beneath the water, and the receivers, by means of which the sound arriving from a distance can be perceived and its direction ascertained.

The two receiving apparatus (Fig. 2) are fitted into the hull below the water-line to the starboard and port respectively. Each of the two is a galvanized iron tank, the upper cover of which is domed, while a metallic diaphragm in the interior is set vibrating by the incoming sound waves so as alternately to close and interrupt an electric circuit. The motion of the diaphragm is transmitted by means of the circuit to the receiver in the pilot house (Fig. 3) in exactly the same way as in the telephone, the whole outfit being nothing else than an application of the telephone principle.

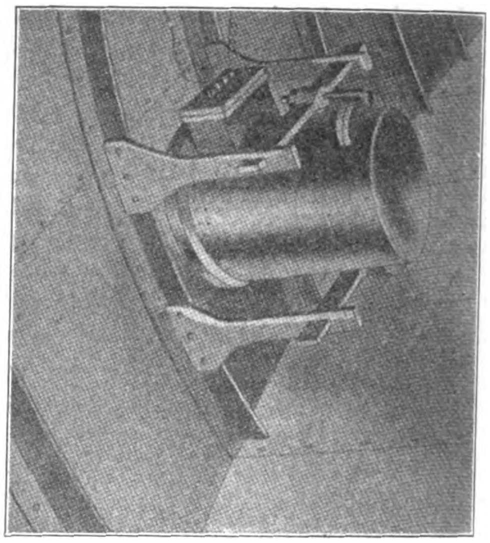

Fig. 2—Receiver Case in Hold of Ship

The working of the receiving apparatus will be readily understood from Fig. 1, their use being as simple as their construction.

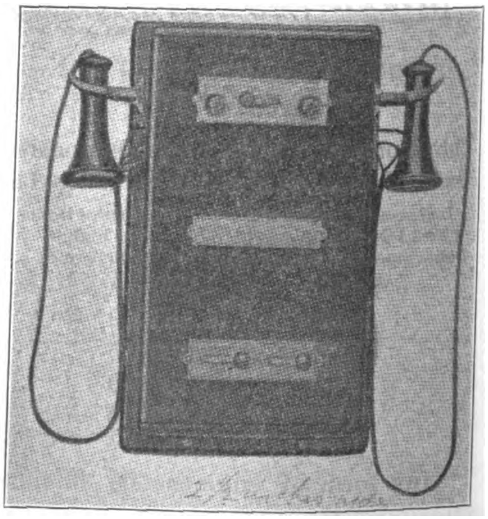

Fig. 3.—Receiving Box in Pilot House.

The vessel at A being on a dangerous course will perceive the sound from the remote submarine bell more loudly through the receiver 1 on the port bow, i.e., on the side turned towards the bell. As the vessel alters her course in the way indicated in the figure, when she is in the position B, the two receivers will give a sound of the same intensity, and she will have gained the direction of the submarine signal, thus avoiding the imminent danger of running ashore. If, on the other hand, the pilot at the beginning had heard more distinctly the sound through the receiver 2 he would have been advised of his vessel keeping the proper course.

---

* From the "Electrical Review," London.

Boston Harbor now has a submarine signal bell not only on Boston lightship but also a similar bell anchored on Harding's ledge, off Point Allerton. Another submarine bell will soon be placed in the middle of the ship channel opposite Boston light, being sunk deep enough to allow all vessels to go directly over it. Sailing masters can then lay a direct course for this bell in thick weather, whereas at present they have to calculate their position by the bell on Boston lightship.

The system of signaling now in use along this coast consists in ringing signal bells on all the lightships. These bells toll out the numbers of the different lightships, 54 for Boston, 73 for Pollock Rip shoals, 66 for Nantucket shoals, etc. There is an interval of two seconds after each beat of the bell, four seconds between numbers, and six seconds before the code is repeated. These bells are rung by steam pressure and work automatically. In clear weather there is no need for sounding the warning bells, which are rung only when the weather thickens and the foghorns are started.

Vessels coming up from New York by the Vineyard in foggy or squally weather listen first for the bell on Vineyard Sound lightship, tolling out 41. Getting their bearings here, they have a good chance for laying a proper course for Pollock Rip shoals, where another guiding bell may be heard.

The sailing master nearing a port or dangerous reef where a lightship is anchored takes down a receiver and moves a lever first to one side and then to the other. The side through which the sound comes indicates that the bell is on that side of the ship. Sound will not travel around a corner under water; it moves in straight lines. Or if, like light, it be reflected, it is so weak as to be readily distinguishable from the sound coming from the same object in a direct line.

Fig. 1 explains how a sailing master can guide a ship by the sound of a submarine bell.

It has been found that the exact position of the bell can be determined in this way to within half a point. As the mariner's compass is divided into 32 points, 8 points marking the angle from east to south, for instance, it will be understood how close to the true direction half a point means.

Another device, for enabling the lookout to stand in front of the pilot house and still listen for the bell, is a flexible speaking-tube running from the telephone on the side of the house. The magnets within the telephone make it necessary to keep it some distance away from the compass.

When this mechanism is understood it is easy to see how readily it can be used for many other purposes than listening for a lightship bell. The screw of an approaching steamer can be heard two or three miles off, for the sensitive microphone in the ship's hold picks up and repeats every sound in the water.

Taking advantage of these facts, the Navy Department at Washington proposes to use the submarine telephone first of all for communication with submarine boats. It has requested the Submarine Signal Company to build a special apparatus for sending messages. This is now being done in the Signal Company's laboratory and workshops, and the instrument is called a multiple sounder. One instrument which is being experimented with has an alphabetical keyboard much like a typewriter. Pressing a key causes a set of hammers to beat on a diaphragm the Morse telegraphic sign for each letter. Anyone who can operate a typewriter can in this way send a submarine message.

A special apparatus somewhat like a stock ticker would enable messages to be picked up on a submarine boat and turned out on a printed tape. In the same way messages could be sent from the submarine boat and received on a shore station, or on the flagship of a fleet. A still simpler way of sending messages, without any special apparatus of this sort, is by attaching a striking gong or bell to the side of a ship and tapping out a certain code. This tapper can be worked by hand, by steam, or by a pneumatic device. Anyone knowing the code can pick up such messages at a distance of from 5 to 12 miles, through a receiving telephone. It is proposed to have a general code for use by all mariners in communicating with lightships, lighthouses, or with all other vessels having submarine telephones. The Naval Department will naturally have a secret code, perhaps the same as is now used in telegraphing.

The first experiment in sending messages in this way took place last summer at Newport. The yacht Chipeta, equipped with sending apparatus, tapped out messages which were received and answered by the submarine boats, Porpoise and Shark, while under water. The submarines had no apparatus for replying. The crude method of striking a hammer against the steel sides of the boat was used, but, it proved effective. A sending apparatus has been put upon a Government tug at Newport, and experiments are now being made by the commandant of the torpedo station there, with a view to introducing this system as a regular part of the submarine boat service. The Dutch Government has made application to the Boston inventors for this same message-sending device to be used on its submarine boats.

United States naval authorities are now looking to the submarine telephone for communicating between the ships of a fleet while in action. It is feared that wireless telegraphy cannot be relied upon then, on account of the concussion of the big guns throwing the delicate wireless coherers out of order. The flag signals are sometimes unseen, owing to smoke or fog arising and dispersing a fleet. So it appears that the submarine telephone will become an exceedingly important part of a navy signal system.

Boston ships were the first to take up the submarine signal invention, even before it was a proved success. The Metropolitan line, plying between Boston and New York, was one of the pioneers. For a year or more the boats of this line have been making their courses into Boston Harbor, and round Cape Cod, guided by the signal bells along this dangerous piece of coast. Other ships, not equipped with telephones, sometimes lie in wait in Vineyard Haven, and, upon seeing a Metropolitan liner, weigh anchor, and steam after her in order to made a safe passage.

The Philadelphia boats have already been equipped with the system; the Merchants and Miners' line boats use it. The North German Lloyd is equipping its entire line, and the Hamburg-American line is also installing it. The Canadian Pacific ships and the Allan liners have likewise installed submarine telephones, while Mr. J. P. Morgan's steam yacht Corsair was the first large steam yacht to adopt it.

Besides being a safeguard for large and costly ships, it is also available for fishing smacks. Two Gloucester fishing boats, the Arkona and Mary L. E. Hardy, now each carry a small and simple submarine signaling outfit. This consists of a pair of ordinary receivers attached by wire ropes to two metal bells containing microphones which are let down on either side of the vessel or dory. There is also a light cell which can be let down in the water from a dory and signals tapped upon it.

WRINKLES.[*]

EDITED BY H. C. ABELL.

Method of Bracing Wooden Tanks of Storage Battery Cells that Have Rotted Out at the Corners.

Large porcelain insulators, such as are used for indoor wiring, were driven in between cells where wood had just started, and if necessary wedged in place by a thin wooden wedge. Tanks braced in this manner are insulated from each other, as would not be the case if wooden wedges alone had been used.

CLEVELAND ELECTRIC ILLUMINATING CO.

Storage Battery Test of Materials for Protecting Copper 'Bus Work in Battery Rooms.

Strips of sheet copper about 0.75 inch wide and 6 inches long were coated with protecting material to be tested and suspended in a bath of sulphuric acid (1.2000 specific gravity) so that they were only partially immersed in the acid. A portion of the upper part of the strip was purposely left bare to observe the effect of acid fumes.

After remaining in the acid for one month the strips were removed and examined.

Their condition was as follows:

1. Strips coated with vaseline; showed no signs of corrosion or sulphating. Coating in as good condition as when first applied.

2. Strip coated with tar; was in the second-best condition of any strip, as no sulphate was formed on that part of the strip not immersed in the acid, but one edge of the immersed portion was sulphated about one-third of its length.

3. Strip coated with shellac; was third best; one edge, however, had peeled off, allowing the acid to attack copper. A portion of the unprotected copper about one-half inch wide was badly sulphated.

4. Strip coated with paraffin; most of the immersed portion of the strip was not sulphated, but from one-half inch below the surface of the acid to the top of the strip was badly sulphated.

5. Strip coated with graphite paint gave results similar to paraffin.

6. Strip coated with heavy, viscous petroleum cylinder oil; badly sulphated entire length.

Vaseline was the only substance that stood the test, but is not entirely satisfactory as a protective on account of its pasty nature.

Experiments were carried out with mixtures of vaseline and paraffin, the latter substance acting as a hardening material. It was found that if over 30 per cent. by weight of paraffin was used the coating cracked slightly and did not adhere properly to the copper 'Bus work was painted with a mixture of 20 per cent. paraffin and 80 per cent. by weight of vaseline, and after three months' use the coating is apparently as good as ever. Dust and moisture can be removed by a soft cloth without injuring coating.

CLEVELAND ELECTRIC ILLUMINATING CO.

Recharging Flashlight Batteries.

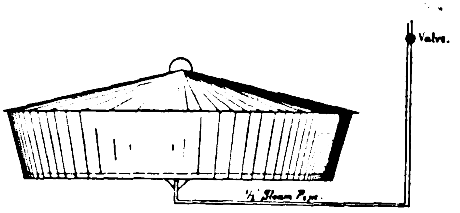
In our meter-readers' room are terminals of the 220-volt direct current, with three 50 cp., 110 volt incandescent lamps in series for recharging batteries.

By placing the battery across these terminals for one or two minutes it is then ready for service again. This prolongs the useful life of the battery at least 100 per cent., in this way cutting down the maintenance on flashlights to a considerable extent.

H. S. RUSSELL, Denver, Col.

Soiled-Waste Cleaner.

I think the drawing of a soiled-waste cleaning arrangement, which I have found very good in my plant, will explain itself.



WASTE CLEANER AND CONNECTION.

We use a galvanized tub to which is connected a half-inch steam pipe, and when the dirty waste is put in we mix with it a box of pearline; after it has boiled for a few hours the waste is taken out and run through a clothes wringer, which puts it in very good shape for use. I do not know whether this is a novel scheme or not, but I offer it for what it is worth.

A. R. SMITH, Demopolis, Ala.

Cleaning Waste and Rags.

We separate out all the oil and a portion of the dirt in the waste and rags by means of a centrifugal washing machine. A machine of this type can soon be made to pay for itself, which we have found out from actual use.

G. H. CUSHMAN, San Antonio, Tex.

WHAT TO DO WITH OUR BOYS.

In an article on the best system of training for engineers, "Engineering" of London prescribes the following course: Taking a bright, strong lad about 16, who wishes to become an engineer; he should go straight from school into the workshops of a medium-sized general engineering works, making, if possible, electrical plant as well as general machinery, as it is necessary nowadays for every engineer to have some knowledge of electricity.

An arrangement should also be made by which the lad does not go to the works on Mondays, but attends instead morning and afternoon or evening classes in engineering at a technical college, thus doing his practical and theoretical work side by side, to the advantage of both. While in the shops the pupil should be encouraged to use his notebook, and to ascertain the labor cost of doing work, also to discover the reasons why the theoretical best forms of machinery are modified in actual practice; and it should surely not be too much to ask that the works manager, in the interests of the future generation of engineers, should give up one or two hours per month to a sort of informal examination of the pupils under his charge, thus ascertaining their progress, and giving them some encouragement to persevere in their work and studies.

The writer is of opinion that the workshop course should follow the course of machinery through the works—that is, the pupil should start in the pattern shop and go on to the foundry, the machine shop and the fitting or erecting room in rotation. A year in each of these four shops should be sufficient to give the pupil a thorough grounding in the practical principles of his profession, and if he shows promise at the end of this time, he should be placed in the drawing office for a couple of years.

At the end of these two years he should go into the accountants' department, and be kept at purely commercial clerical work for another year, after which he might go into the estimating department for two years more, and, provided always that the lad has shown enough ability to justify his being given these opportunities, at the age of 25 we have a young engineer admirably adapted for a post as assistant manager, or even as manager, provided again that he is possessed of the power of ruling others, which is, of course, a physical characteristic, and has little or nothing to do with training.

---

[*] Paper presented before the National Electric Light Association at its 28th convention, held at Denver-Colorado Springs, Col., June 6-11 1905.

Electric Vehicles Show Progress.

For the purpose of proving that the generally accepted theory that electric automobiles are of little value for long-distance work, and that their range is limited to city streets, two leading manufacturers of this class of vehicle in France have recently conducted a series of tests over the roads from Paris to Trouville, a distance of 130 miles. The results were a surprise, and indicate a great advancement in the construction of batteries. The cars that were used were heavy town vehicles, but they succeeded in making speeds that on stretches of 50 miles averaged from 16.7 to 28 miles an hour.

The first test was made by M. Vedrine with two cars, a three-seated cab weighing 3,476 pounds and a landau weighing 3,960 pounds. The cab carried three passengers and the laudau four. The start was made at St. Germain. For the first 52 kilometers the cab made a speed of 24.2 miles an hour. At Evreux both cars were recharged and the run was completed in 5 hours, 35 minutes and 13 seconds after the start, the average speed being 20.8 miles over good but hilly roads. The landau averaged 16.7 miles an hour.

The success of M. Vedrine induced M. Krieger, another manufacturer, to test two of his cars over the same road. His cars were a closed coupe weighing 3,498 pounds, and an open landaulet weighing 3,938 pounds. Both recharged at Evreux, having made the run to that town at a speed averaging 20.8 miles an hour. The same average was maintained for the remainder of the trip, the total running trip being 4 hours, 50 minutes and 13 seconds for the coupe and 4 hours, 22 minutes and 8 seconds for the laudaulet. M. Vedrine started the same day with a four-seated closed coupe and ran from St. Germain to Trouville without recharging at an average speed of 18 miles an hour.

Merit Marks a Success.

So effective has the "Brown System of Discipline," employed in public schools and colleges, proved with the 12,000 employes of the Brooklyn Rapid Transit Company, that it has been installed as a permanent feature of the company's policy toward its employes.

The system provides for a series of merit and demerit marks which are accorded each of the motormen, conductors and switchmen for good work or bad. Sixty demerit marks constitute a dismissal. Good behavior for three months entitles the employe to five merit marks, which cuts down his demerit marks an equal number. Impudence, carelessness and intemperance are some of the sources of demerits.

Proposals Invited.

The Bureau of Supplies and Accounts of the Navy Department at Washington is inviting sealed proposals until October 31 for furnishing Eastern navy yards with the following supplies: Schedule 181, incandescent lamps; schedule 182, electric soldering irons. Prospective bidders can obtain blank proposals and detailed information of the above by applying to the Bureau at Washington, or to the Navy Pay Office in New York for Eastern Yards.

New York Electrical Society.

The New York Electrical Society will hold its opening meeting at the Edison Station, 27th street near 6th avenue, on Monday evening, October 23. Mr. Peter Cooper Hewitt will lecture on "Electrical Reactions of Gases."

Armour Institute of Technology.

The Armour Institute of Technology, 23d and Armour avenues, Chicago, is offering evening classes for the session of 1905–1906 in mechanical, electrical, telephone, civil, chemical and fire-protection engineering, with drawing, practical shop work and mathematics.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCT. 10, 1905.

Electric Railways and Appliances.

801,226. Trolley for Electric-Railway Vehicles. Harry P. Davis, Pittsburg, and Christian Aalborg, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company. Filed March 6, 1905.

801,335. Trolley. Eugene J. Parker, Providence, R. I. Filed Dec. 23, 1904.

801,363. Motorman's Valve. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed April 27, 1903.

801,602. Electric Locomotive. Lincoln Moss, New York City, assignor to the Robins Conveying Belt Company, same place. Filed Feb. 2, 1904.

801,631. Apparatus for Controlling the Operation of Railway-Switches. Charles C. Anthony, Philadelphia, Pa. Filed March 6, 1905.

801,718. Trolley-Harp. Charles L. Hooper, Rochester, N. Y. Filed Dec. 27, 1904.

801,733. Automatic Block-Signal System. Ross Logsdon and Elza S. Stotts, Perry, Ia., assignors of one-third to Bayard T. Linley, Des Moines, Ia. Filed Jan. 18, 1904.

Electric Lights and Appliances.

801,261. Electric Lighting System. Granville E. Palmer, Boston, Mass., assignor of one-half to Charles B. Price and Frank S. Price, same place. Filed Nov. 6, 1903.

801,364. Safety Device for Lamp-Signals. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Feb. 19, 1904.

801,637. Electric-Arc Lamp. Emile Batault, Geneva, Switzerland. Filed July 19, 1902. Renewed March 1, 1904.

801,664. Adjustable Electric-Lamp Holder. Henry F Holtmann, Indianapolis, Ind. Filed Nov. 23, 1904.

Electrical Machinery and Apparatus.

801,214. System of Motor Control. Frank E. Case, Schenectady, N.Y., assignor to the General Electric Company. Filed July 2, 1904.

801,224. Automatic Electric-Motor Starter. William M. Cummiskey, Newark, N. J. Filed July 20, 1904.

801,230. Emergency and Vacuum-Breaking Valve Mechanism. William L. R. Emmet, Schenectady, N. Y., assignor to the General Electric Company. Filed April 5, 1904.

801,238-239. Means for Controlling Circuit-Breakers and Control Apparatus. George H. Hill, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 8, 1904, and March 1, 1905.

801,243. Electric Measuring Instrument. Frank Holden, Rugby, Eng., assignor to the General Electric Company. Filed Jan. 2, 1904.

801,245. Electrical Controller. Henry D. James, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Feb. 27, 1905.

801,250. Supporting-Clamp for Electric Conductors. James R. Kearney, Topeka, Kan. Filed Dec. 15, 1904.

801,255. Armature Cross Connection for Electrical Machines. Chester B. Mills, Wilmerding, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Oct. 20, 1904.

801,285. Electric Controller. Robert Wellens, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Dec. 19, 1904.

801,288. Quick-Break Electric Switch. Herbert C. Wirt, Schenectady, N. Y., assignor to the General Electric Company. Filed March 5, 1902.

801,355. Self-Propelled Vehicle and Method of Controlling the Same. Ernest J. Berg, Schenectady, N. Y., assignor to the General Electric Company. Filed April 20, 1904.

801,357. Governing Mechanism for Turbines. John G. Callan, Lynn, Mass., assignor to the General Electric Company, Filed March 30, 1905.

801,399. Governing Mechanism for Turbines. Richard H. Rice, Swampscott, Mass., assignor to the General Electric Company. Filed April 1, 1905.

801,419. Electric Measuring Instrument. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed Feb. 15, 1905.

801,441. Electric Switch-Throwing Device. Louis H. Coxe, Philadelphia, Pa. Filed Nov. 12, 1904.

801,487. Controller. Leonard A. Tirrill, Lynn, Mass., assignor to the General Electric Company. Filed June 3, 1904.

801,497. Electric-Meter Bearing. James J. Wood, Fort Wayne, Ind. Filed Nov. 8, 1904.

801,536. Face-Plate for Electric Switches. Norman Marshall, Newton, Mass. Filed Jan. 19, 1905.

801,588-589. Transformer Cut-Out. John P. Hetherington, Logansport, Ind. Filed Dec. 15, 1904, Jan. 4, 1905

801,784. Automatic Electric Switch. William S. Guthrie, Terrell, Tex. Filed Nov. 29, 1904.

Telephones and Telephone Apparatus

801,231. Index Attachment for Telephones. Fred E. Farmer, Alliance, O. Filed April 28, 1905.

801,308. Lock for Automatic Telephone-Switch Shafts. John Erickson, Chicago, Ill., assignor to the Automatic Electric Company. Filed Dec. 31, 1904.

801,778-779-780. Telephone System and Apparatus and Telephonic Apparatus. Charles E. Egan, Chicago, Ill., assignor to the Egan Electric & Telephone Manufacturing Company, Petersburg, Ill. Original application filed Sept. 29, 1904. Divided and last application filed Aug. 16, 1905.

Miscellaneous.

801,380. Apparatus for Electrostatic Separation of Substances of Diverse Electric Susceptibilities. Charles H. Huff, Brockton, Mass. Filed Aug. 6, 1904.

801,509. Signal System. Valentin Chisholm, Rockland, Me. Filed April 14, 1905.

801,578. Range-Finder. Bradley A. Fiske, New York City, assignor to the Western Electric Company. Filed Nov. 25, 1902.

801,774. Conduit for Electric Cables or Conductors. Thomas E. Devonshire, London, Eng. Filed Nov. 5, 1904.

801,800. Signaling Through Submarine and Like Cables. Oliver J. Lodge, Birmingham, and Alexander Muirhead, London, Eng. Original application filed Oct. 3, 1904. Divided and this application filed April 25, 1905.

801,823. Automobile. Ernst J. Berg, Schenectady, N.Y., assignor to the General Electric Company. Original application filed April 20, 1904. Divided and this application filed May 22, 1905.

Reissue.

12,393. Leading-In Wire for Incandescent Electric Lamps. Thomas A. Edison, Llewellyn Park, N. J., assignor to the Edison Electric Light Company. Filed July 12, 1905, Original No. 444,530, dated Jan 13, 1891.

THE TELEPHONE WORLD.

Big Plans for New Company.

Thomas W. Finucane, president of the United States Independent Telephone Company, arrived in New York City last week and took up his headquarters at No. 31 Liberty street. In an interview he said:

" For six months engineers have been mapping out the territory in which the Independent company will begin work. Fifty switchboards and 15 exchange buildings have been located, leases for which will be signed when the engineers have overseen the laying of cables and telephone wires.

" Not one contract will be solicited until we are ready to install our telephones. We will then give New York service in one-half the time it now takes to form a connection. We have simply profited by the experience of the corporation which controls the telephone system in New York. The rates will be materially lower. Our lines are down to Peekskill and we will be in New York without loss of time.

"Application has been made to the Empire City Subway Company for service, which we demand under our franchise originally granted to the Mercantile Electric Company, and absorbed by the New York Independent Telephone Company.

" There is nothing private or hidden about the United States Independent Telephone Company. It was organized for the express and particular purpose of making money for its stockholders and for giving to the citizens of New York and other cities in this country the best telephone service that they ever knew anything about and at a much lower rate than they are now paying. We are going to do both. We have the money to keep up our end. When the New York plant is in operation the system will extend from here to Utah."

Ericsson Company Will Build Factories.

The Ericsson Telephone Company, the largest manufacturers of telephones and telephone supplies in Europe, is preparing to establish a telephone system in Mexico.

The company also intends to erect large workshops at Buffalo, N. Y., the power for which will be obtained from Niagara Falls.

The first annual meeting of the stockholders of the Sioux City, Ia., Telephone Company was lately held. The old board of directors was re-elected by the 40 stockholders, which comprised about four-fifths of the total number of persons holding shares in the company. The board consists of T. A. Thompson, E. W. Rice, D. S. Lewis, F. L. Eaton, W. P. Manley, Howard S. Baker and George C. Scott. President Thompson and Secretary Scott made their annual reports and addressed the stockholders as to the prospects of the company, which both held to be very bright. Mr. Thompson reported that 1,600 'phones had been installed.

A recently organized concern, known as the Austinburg, O., Telephone Company, is backed by F. M. Houghtaling, Tracy D. Herrick, G. H. Webb, M. B. Andrews and W. W. Barnes.

An Independent telephone line is being built between Richland and Sheridan, Pa., and touches a number of thriving towns.

Severe Terms for Independent Company.

Independent telephone operations in New York City received a setback Friday when Controller Grout, presented to the Board of Estimate a special report of Engineer Harry P. Nichol, of the Finance Department, on the value of the franchise sought by the Atlantic Telephone Company. Under the terms as fixed by Mr. Nichol, the company would have to pay the city $7,750,000 in 25 years as a minimum for the privilege of entering the local field to compete with the New York Telephone Company.

These terms are regarded by the Independent companies as unnecessarily onerous, being much more severe than the terms imposed upon the New York Company. The Independent company is willing to furnish telephones at half the rate charged by the Bell Company.

The New York Telephone Company pays the city practically nothing for its franchise. It is taxed on its real estate and on its franchise as real estate, under the franchise tax law. The Independent telephone companies, however, will be taxed likewise under the State statutes. For its franchise rental the Bell company should pay the city through its ownership of the Empire City Subway; but its payments through this source have been held up for years, with the result that the city has been obliged to begin what seems to be interminable litigation without being able to get the company to pay anything.

The Missouri & Kansas Telephone Company has closed a contract for an exchange at Colwich, Kan. The exchange will be put in by a company composed of Colwich business men, and will be operated in connection with the Missouri & Kansas service. This will give the wholesalers of Wichita direct telephone connection with the Colwich business men. A reduced rate has also been put into effect between Colwich and Wichita.

The telephone war at Foley, Minn., in which the Northwestern Telephone Company, the Twin City Telephone Company, the village council and citizens in general have been more or less involved, was ended at a meeting of the village board lately, when it was unanimously voted to grant a franchise to the Northwestern Telephone Company. This franchise carries with it the privileges of the streets.

The directors of the Great Eastern Telephone Company, lately incorporated in Albany, N.Y., are William H. Schack, Eugene P. Brock, Elias J. Seach, Egbert A. Reynolds, William Reynolds, of New York City, and Stephen B. Conger, of Brooklyn.

A new telephone company has been organized at Springtown, Pa., with H. S. Funk as president; H. H. Funk, secretary, and J. S. Weierbach, treasurer, to connect upper Bucks County towns.

The Decatur County Mutual Telephone Company of Leon, Ia., was lately organized with a capital of $10,000 by E. J. Harney and others.

The Sunset Telephone Company's wires are being put underground in Palo Alto, Cal.

Independent Companies Merge in Southwestern Kansas.

A charter has been granted the Citizens' Home Telephone Company, a corporation with a capitalization of $500,000, organized for the purpose of taking over and consolidating all the Independent telephone companies in Southwestern Kansas. The incorporators are James Plottner and George Yeager, of Kansas City; Fred Perkins and D. J. Romino, of Oswego; George Spangle, of Chetopa, and C. H. Kimball and F. H. Brown, of Parsons. The general offices will be located in Parsons.

The companies to be consolidated are: Pittsburg Home Telephone Company, Galena Home Telephone Company, exchanges at Galena, Weir City and Scammon; Labette County Telephone Company, exchanges at Oswego, Chetopa, Altamont, Mound Valley, Edna and Bartlett, and the Parsons Home Telephone Company.

The consolidated companies have a total of 3,000 'phones, and over 400 miles of toll lines. A copper circuit will be put in from Pittsburg, connecting with the St. Louis and Kinloch long distance lines by way of Parsons to Cherryvale, where it will connect with the Kansas City Home Telephone Company's long distance lines.

The Home Telephone Company of Los Angeles, Cal., has bought a site for its new building, which will be erected soon, and in which will be installed the new automatic apparatus which will displace the manual now in use at the main office, so that the entire system will in the near future be completely automatic.

The Long Distance Telephone Company of Los Angeles, Cal., has opened new offices in the Currier Building and begun the installation of new switchboards for increased facilities. It is installing a new 25 pair cable between Los Angeles and Pasadena, the new lines are working to Riverside and the San Diego lines are nearing completion.

President Zimman, of the Omaha, Neb., city council, announces that he will introduce an ordinance demanding a "substantial" reduction in the charges for telephones by the Nebraska Telephone Company. He says he has assurances that it will be passed by the council.

A special meeting of the stockholders of the New York & New Jersey Telephone Company will be held in Brooklyn, N. Y., October 25 to vote on a proposition to increase the capital stock from $15,000,000 to $50,000,000. The authorized stock was increased in March, 1901, from $8,000,000 to $15,000,000, and all except $1,220,900 has been issued.

The Ticonderoga Home Telephone Company was incorporated last week with a capital of $25,000. The directors are J. A. McLaughlin, Putnam; R. N. Clemens, Dresden; D. C. Bascom, of Ticonderoga, N. Y.

M. A. Joy, of Terrell, Tex., has made application to that city council for a franchise to operate a telephone company. A committee has been appointed by the council to consider the application.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Appleton, Wis.—A co-operative electric plant is being projected in this city by some of Menasha's business men.

Charles City, Ia.—A deal was lately made whereby the electric light company passed from H. V. Fussell & Co. to F. O. Martin, of Floyd, and A. L. Dodd, of this city. The last-named gentlemen recently purchased the water power at Floyd, and will use it to furnish power for the light plant at this city, transmitting the electricity some six miles by means of a feed wire.

Coalville, Utah.—The city council has approved the plans and specifications for the power house for the electric light plant.

Columbus, Ga.—A resolution recently offered by Alderman Newman was adopted by the city council and a committee appointed to investigate the cost of establishing a municipal lighting plant here.

Columbus, O.—While plans have not yet been definitely decided upon, it is probable that the directors of the new First National Bank will soon ask for prices on a complete independent electric lighting plant for their new building.

Conroe, Tex.—The Southern Pine & Cypress Company of Houston will establish a planing mill and electric lighting plant.

Crawfordsville, Ind.—J. F. Davies has been awarded the contract for repairing the Crawfordsville municipal electric lighting plant, for $8,538.

Defiance, O.—At a recent meeting of the city council a resolution was introduced declaring it necessary to bond the city in the sum of $50,000 for the purpose of erecting and maintaining an electric lighting and gas plant.

Fayetteville, N. C.—This city is arranging to make extensions and improvements to its electric light plant.

Highlands, N. J.—An election will be held November 8 to vote on the question of issuing $25,000 in bonds for the installation of water and an electric light system.

Kimball, Wis.—The Superior Construction Company of Houghton has been awarded a contract to build and install an electric lighting plant for the Kimball & Clark Company.

Lawrence, Kan.—The Lawrence Electric Light Company has been granted a franchise to furnish electricity for light and power throughout this city.

Morehead, Ky.—The Morehead Electric Light Company has been organized by citizens here. The poles are being placed in position, and all arrangements made for installing an electric light plant.

Newport, R. I.—A matter of interest which recently came up before the city council was the authorizing of the committee on street lighting to ask for proposals for bids for the installation and erection of a municipal electric lighting plant, this being mentioned, as the present contract for lighting the streets by electricity expires on November 15.

Oakdale, Ky.—The American Electric Lighting Company, a concern recently incorporated and of which A. F. Steber is president, has secured a contract with the board of trustees of this place to furnish lights for a term of five years.

Rockmart, Ga.—This city contemplates issuing bonds for the construction of an electric light plant. Address the mayor.

Russell, O.—Messrs. Fullerton and Wilson, of Greenup, have been awarded a franchise to erect an electric light plant here for the purpose of supplying domestic and street lighting.

Van Buren, Ark.—The Van Buren Electric Light & Power Company has been incorporated with a capital of $25,000, by John E. Powers and Sidney A. Pernot.

Warsaw, Mo.—This town has voted affirmatively on the proposed $6,000 bond issue for erection of an electric light plant. The town clerk may be addressed.

West Terre Haute, Ind.—The town board in adjourned session granted a franchise to the West Terre Haute Light & Power Company. The company is composed of Claude Erwin and Samuel C. Stimson. The franchise provides for the construction and operation of an electric light and power plant.

STREET RAILWAYS.

Anderson, S. C.—An application for a charter for a trolley line to Ensley has been made. The capital stock of the company is $100,000 and incorporators R. Frank Smith and Joseph J. Long.

Barrington, Ill.—A new trolley line is projected from Chicago through Cook, Lake and McHenry Counties, the object being to connect Lake Geneva with Chicago.

Brillion, Wis.—O. C. Henke has returned from New York in the interests of the Fox River Valley Electric Railway, and reports that all obstacles have been overcome and that the construction of the line at an early date is assured.

Canton, O.—The power house of the Canton-Akron Electric Railway Company was lately destroyed by fire, causing a loss of about $45,000.

Crete, Ill.—Arthur Burns, who is interested in the Chicago & Kankakee line, has been here to procure the right of way for the new electric road which will be built through this city this fall.

Danville, Pa.—At a recent meeting of the council application was made by the West Branch Electric Street Railway Company for the right of way over certain streets in this city.

Findlay, O.—The Sandusky, Fremont & Tiffin Traction Company has been incorporated with a capital of $100,000. Charles Thompson and W. H. Gilcher are the incorporators.

Frederick, Md.—The sale of the Frederick & Middleton Electric Railway to the Baltimore & Frederick Electric Railroad Company was lately consummated.

Muncie, Ind.—George F. McCulloch has stated that an electric line is to be built from Kansas City to Topeka.—The Delaware County commissioners have granted a franchise to the Indianapolis, Newcastle & Toledo Electric Railway Company, which proposes to build a traction line from Newcastle to this city.

Nelsonville, O.—The Nelsonville, Athens & Glouster Traction Company has been incorporated with a capital of $10,000. The incorporators are L. F. Carpenter and J. P. Reynolds.

Newark, N. J.—President Underwood of the Erie, recently said: "A committee is considering the electrical equipment of the line. At first this equipment will be in suburban territory. It has been demonstrated that electrical service is all right there. Arrangements are being made for the installation of the most modern and efficient railway signal service in the market."

Omaha, Neb.—The proposed electric line from this city to Griswold may enter Council Bluffs.

Owingsville, Ky.—The Olympian Springs Company, composed of Lexington capitalists, has about decided to build an electric railway from the springs to this town.

Pekin, Ill.—The village board of Tremont has granted to the Bloomington, Pekin & Peoria Interurban Railway Company a 50-year franchise to operate and maintain an electric railway in and through that village.

Plainfield, Ill.—An electric line is to be constructed connecting this place with Naperville, Wheaton and other towns in Du Page County and giving a direct electric railway connection from the capital of Will County to the capital of Du Page County.

San Francisco, Cal.—A railroad deal affecting this city and San Jose and the intervening peninsula has been perfected here. L. E. Hanchette has bought for $500,000 in cash the Santa Clara Interurban Railroad Company. He has also purchased for $800,000 the San Jose & Santa Clara Railway Company. Of the purchase price he has paid down $50,000 in cash to bind the bargain.

Wabash, Ind.—With a capital of $50,000 the Wabash & Northern Traction Company has been incorporated by J. A. Barry and Lincoln Guynn.

Wheeling, W. Va.—A force of surveyors for the proposed Belmont Electric Railway is working over the streets of this city, taking measurement for the new line in order to get affairs in shape and ask for bids for its construction.

POWER PLANTS.

Bellingham, Wash.—Stone & Webster, of Boston, whose purchase of the Nooksack Falls power plant from the Bellingham Bay Improvement Company, was announced a short time ago, will immediately spend $200,000 in completing the plant to a capacity of 2,000 hp., with ultimate plans to invest $1,000,000 and guarantee 25,000 hp.

Hartford City, Ind.—Architect Weatherhogg, of Ft. Wayne, is preparing plans for the erection of a new power plant for the Wayne Paper Mill in this city.

Provo City, Utah.—L. L. Nunn, of this place, manager of the Telluride Power Company, is contemplating the erection of a big power plant on the Duchesne for the purpose of furnishing heat and light for Park City, Salt Lake City, Bingham, Mercur, Eureka, Price and other places in the State.

Rome, Ga.—A large electric power plant is to be built on the banks of the Etowah River between this city and Cartersville The capital stock of the company is $400,000. R. L. West, of Atlanta, is one of the promoters.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅜@16⅝c.; Lake 16⅜@16⅝c.; casting, 16⅛@16⅜c.

At a directors' meeting of the Crocker-Wheeler Company, at Ampere, N. J., the regular quarterly dividend of 1¼ per cent. was declared.

The directors of the Coney Island & Brooklyn Railroad Company have been re-elected. They will meet to-day (October 18) to elect officers.

The Metropolitan Street Railway Company of New York has applied to list on the Stock Exchange $1,284,000 additional refunding 4 per cent. bonds of 2002.

The Grand Rapids (Mich.) Railway Company has declared the regular quarterly dividend of 1¼ per cent. on its preferred stock, payable November 1 to holders of record October 18.

A financial writer says "the stock market just now very much resembles an electric fan. It is refreshing and entertaining to look at, but if you get too close to it you are liable to get hurt."

The Milwaukee Electric Railway & Light Company has declared the regular quarterly dividend of 1½ per cent. on its preferred stock, payable October 21. Books close October 20 and reopen November 1.

The twentieth annual report of the Edison Electric Illuminating Company of Boston shows a surplus of the interest and dividends of $71,415, against $77,408 in the previous year. There was, however, an increase in interest and dividends of nearly $100,000 last year.

The Hudson Street Railroad Company filed articles of incorporation Monday in the county clerk's office at Jersey City. The capital stock is $3,000,000 and the object of the company, as given in the papers, is to construct and operate street railway lines in Hudson County, N. J. The new lines are to tap the tunnels to New York.

The Pacific Gas & Electric Company has been chartered in San Francisco with a capital stock of $30,000,000, consisting of $10,000,000 six per cent. cumulative preferred and $20,000,000 common. This is the company formed by N. W. Halsey & Co. to take over the California Gas & Electric Corporation and the San Francisco Gas & Electric Company.

The stockholders of the Hartford (Conn.) Electric Light Company have accepted the charter amendments authorized at the last session of the Legislature, allowing an increase in the company's bonds and capital stock. It was voted to increase the capital from $1,600,000 to $1,800,000 by the issue of $200,000 new stock at par to present shareholders. This is at the rate of one new share for each eight shares of stock now outstanding, so that eight rights will stand for one new share.

The annual report of the New York City Railway Company, for the fiscal year ended June 30, 1905, shows the actual earnings on the $52,000,000 Metropolitan Street Railway Company stock to have been 16-10 per cent., compared with 4 3-10 per cent. earned the previous year. The gross income for the last fiscal year was $9,061,304. Total deductions for interest, rentals, etc., exclusive of the 7 per cent. dividend guaranteed on Metropolitan Street Railway stock, amounted to $8,218,246, leaving a surplus, before the payment of the 7 per cent. Metropolitan dividend of $843,058, or 16-10 per cent. on the stock.

EDITORIAL NOTES.

Elevator Development.

Skyscrapers are the proofs that may be offered to show the degree of success attained in elevator construction. It is quite evident that these most noted architectural features of New York are the result of conclusions in the field of elevator construction which indicate the safety, speed, economy and popularity of the modern electric elevator.

Survival of the fittest is the only adequate expression to use in explaining why the electric elevator has taken the most prominent place of all in the development of this class of apparatus. The steam elevator and hydraulic elevator were at one time the only ones in use, but gradually their position was usurped by the electric, which is now considered, and worthily so, the type of elevator in every way best suited to the equipment of a tall building, a hotel or an apartment house. The application of the motor to the raising of a weighted mass between guides at first sight seems a simple enough problem. But the discouraging features which appear are not entirely those which relate to the lifting of the car. They relate to the lowering of it, and for that reason, because that rate must not be too rapid on account of the human freight on board, the problem has become accentuated. Means by which the descent, however rapid, is checked, and the final stop made in a gentle manner, represent one of the triumphs of electric elevator construction. In an hydraulic device the simple regulation of the flow of water under pressure will delay the movement of the large piston rod projecting from the cylinder, controlled by the water. But in an electric elevator it was necessary to utilize more scientific principles in order to avoid the rude shock of concussion at the bottom of the shaft. The problem of lifting the car offered only one difficulty, which was that of holding it securely when the power was off. Either the lifting cable governed this, by being itself checked, or the car was held by means of brakes. The former, as may be noted, was adjudged the best, and in consequence the necessity for performing this operation gradually, though within a very short period of time, was as necessary in stopping as in starting. Without entering into the technicalities relating to this phase of elevator design and construction, the fact to be observed is, that all of these things have been splendidly accomplished. In consequence safety, speed, economy and popularity have been the final and admitted features of this indispensable form of machinery.

The readiness with which business men are willing to occupy the fifteenth or twentieth floor of a skyscraper, a dangerous altitude at the best, is because they rely upon the elevator for rapid exit. Let it be believed that the elevators of large buildings are defective, and the exodus from such would be in volume and rapidity one of the traditions of New York. The electrical engineer has not only given these huge monuments of architectural skill their light, but their most highly prized feature, a safe and fast elevator as well.

Trade With the Philippines.

It is interesting to note, and in the face of criticism to the contrary, that our exports to the Philippines are slowly on the increase, and this at a time when the entire importations into the islands show a decrease. Taking the total importations from all sources for the ten months ending April, the latest period for which complete returns are available, we find that a slight increase was shown from that of $27,006,381 in 1903 to $28,344,971 in 1904, decreasing again in 1905 to $24,966,193, the largest decreases being in the importations from Asiatic countries, where the decrease as compared with the returns of last year has been from $15,172,881 to $10,809,724. On the other hand, the returns show that the importations from the United States during the first ten months of 1903 amounted to $3,380,855, in 1904 to $3,788,111, and in 1905 to $4,514,259.

There has for some time past been a tendency in certain quarters to minimize the growth of our trade in the Philippines during the period which has elapsed since our occupation of the islands. It must be remembered that there are peculiar conditions existing which do not always maintain upon the acquirement of new possessions. Previous to our acquirement of the islands there had been a very limited demand for our goods, and under the change of regime the American exporter has not found any special privileges to induce him to follow the national flag; and it should not seem to be a matter for criticism that after seven years we have not appropriated to ourselves the entire trade of the islands and have diverted it radically from the channels in which it has long been established.

Owing to the Russian-Japanese war the fiscal year figures for 1905 represent a disturbed condition of Eastern trade unsuitable for comparative commercial purposes, but a study of our exports for the previous year are of interest in connection with a showing of what the American exporter is doing in our insular possessions—a showing not without credit except to those anticipating a commercial conquest of the islands in too short a time after we have acquired them.

That the present $5,000,000 worth of exports of American goods to the islands, which has raised the United States from an insignificant rank to a foremost place in the Philippine trade, is in considerable measure due to the presence of the flag with its contingent of Government employes having preference for American goods is no doubt true, but in the large increase there is still enough left to indicate an active and healthy export trade, and there is matter for satisfaction at the record made by the American exporters in a brief period against established competitors in this new field.

Statistics show that we are the leading source of supply in telegraph, telephone and other electrical instruments. For the first ten months of the past fiscal year we supplied $31,990 out of a total importation of $48,434, our nearest competitor being Germany with a value for the same period of time of only $5,180. Under the heading of incandescent lamps, we supplied $3,057 out of a total supply value of $5,718; here again Germany was second, the value being $867. Out of a total importation during that period of $30,597, we contributed $16,572, or more than one-half. Under this heading our nearest competitor was Great Britain, with her value of $5,287. Under the heading of electrical machinery we supplied $106,446, out of a total value of $112,784. This is certainly not a showing to be despised.

J. C. R. Laflamme, president of the Royal Society of Canada, has been appointed by the International Waterways Commission as geological expert to make a report upon receding of the Canadian side of Niagara Falls. It is said the Canadian side has receded 300 feet in 80 years.

◆

The Franklin Institute's programme of lectures for the winter season includes Dr. F. A. C. Perrine, of New York, on "Power Transmission," and Charles E. Waddell, electrical engineer of the Biltmore estate, Biltmore, N. C., on "Forest Denudation and Its Effects."

◆

A dispatch from Milwaukee Wis., to the New York "Times" (October 20) says: "The Bullock Electric Company of Cincinnati has been absorbed by the Allis-Chalmers Company of Milwaukee, and the General Electric Company has purchased the majority of the Allis-Chalmers common stock. According to reports, E. C. Converse of Pittsburg, as the result of a deal, has been made a director in all three companies. Only a few weeks ago the capital stock of the Bullock Company was increased to $3,000,000 to enlarge the plants. The Allis-Chalmers Company, a rival of the General Electric, leased the Bullock Company in March, 1904. The price at which the General Electric obtained control, it is reported, was $25 a share for the common stock."

◆

An expert in the manufacture of rubber gloves for electricians states that while testing with water is a good way of finding imperfectly made joints, it is of no use for finding defects in material, such as grit or air bubbles below the surface. These are quickly found by a high voltage test with alternating current in water, without which test the use of the gloves may be more dangerous than their neglect. Every pair of gloves, says the London "Electrical Review," should be certified to have passed an alternating current test at 5,000 or 10,000 volts, according to the requirements. It is useless to test a sample pair, where human life is at stake, and every engineer purchasing such gloves should insist on an adequate guarantee of their reliability as stated above.

◆

It was voted by the corporation of the Massachusetts Institute of Technology in Boston to withdraw every proposal looking to a merger with Harvard University.

◆

The principal reason for the delay of the Grand Trunk Railway Company in equipping the St. Clair tunnel with electricity is that the company's engineers are investigating the feasibility of Niagara power.

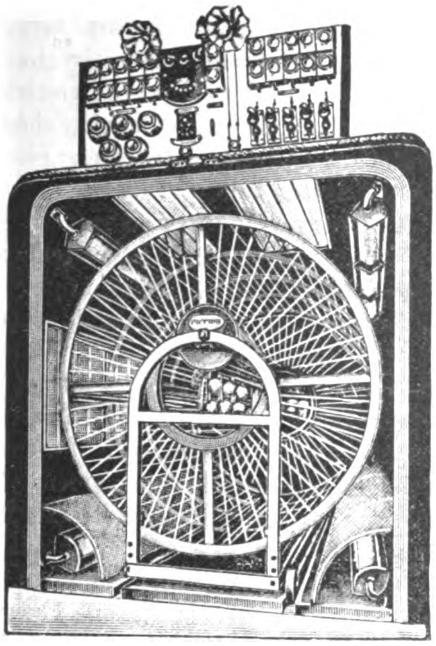
◆

The direct telephone line between Bucharest and Buda-Pesth was nearly completed on September 1, and it was announced would soon be put into regular service. The Roumanian service is fixing the line between Sinaia and Predeal, whilst the Hungarian service is fixing the line between Predeal and Brashov, where the direct line with Buda-Pesth is joined. When this line is finished, Bucharest will be in telephonic communication with two centers of international communication, viz., with Buda-Pesth via Predeal and Brashov, and with Sofia by the direct line between Bucharest and Giurgevo, the Danube cable between Giurgevo and Roustchouk, and the direct Bulgarian telephonic line between Roustchouk and Sofia.

SOME NOVELTIES OF THE LONDON ELECTRICAL EXHIBITION.

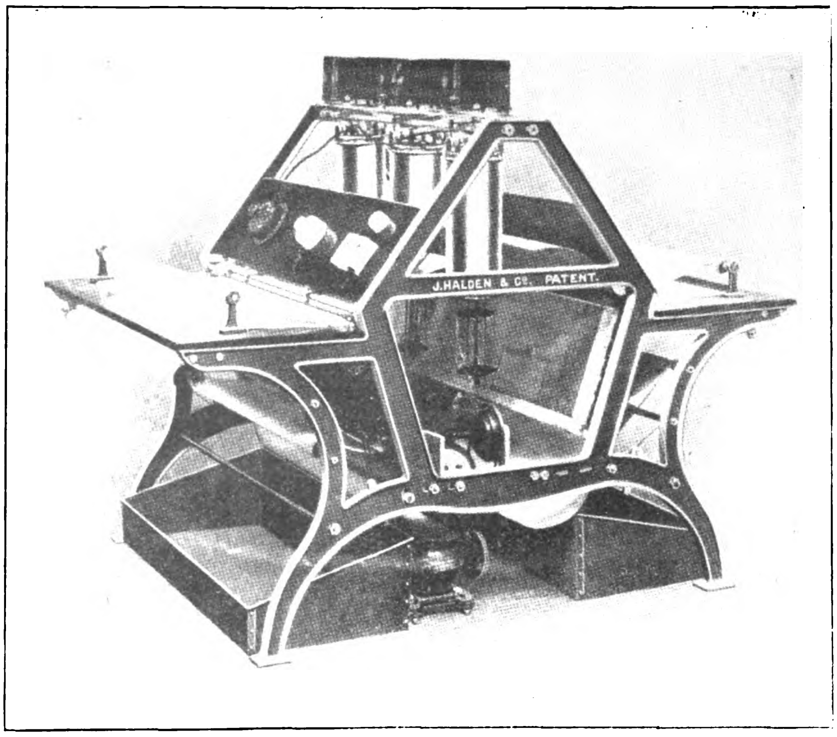
(From our London Correspondent.)

A feature at the London Electrical Exhibition possessing considerable novelty, and one which promises to be of commercial utility, is noticeable in the form of an electric disinfector for use in hotels, nursing and medical institutions. We give an illustration of this. It consists of a large metal chamber 7 feet in height by 9 feet long and 6 feet wide, fitted with the Dowsing system of heating by means of powerful electric lamps. In the center of the chamber, it will be observed that there is a rotating cage with five sections, into which bedding and other articles can be placed for disinfection. The system employs simultaneously both light and heat to kill the germs of disease, and of course the use of steam and chemicals is dispensed with entirely. The temperature employed is from 300 to 350 degs. Fahr. It is believed that this is the first attempt to use light rays for the destruction of disease germs in bedding and clothing on the lines of Finsen's discovery. Another application to which this Dowsing disinfector is being put is in the treating of moth-eaten articles, the effect of the light and heat treatment being to kill the insects and their eggs. It is interesting to mention here that central works are to be erected shortly in London, where the apparatus will be available for the treatment of articles for the public.



Electric Disinfector for Hospitals.

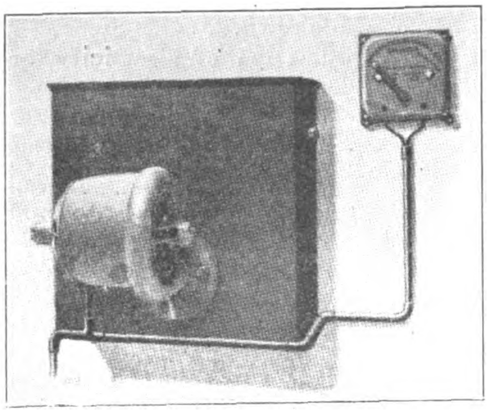
A device which especially appealed to the domestic tastes was the Bonis patent electric sweeper, cleaner and ventilator. This is a portable arrangement, consisting of an aspirator with motor and suction attachment, and a separator or dust filter. A motor of one-sixteenth horse power is used. The brushes, which are attached to a hollow pole like a broom handle, or moved by hand, are bell-shaped in form, having the bristles arranged around the outer rim in such a manner that the air can pass freely through them. The suction produced in the center of the brush by the motor draws into the receptacle the dust, dirt, fluff, etc., removed in the sweeping. India-rubber brushes are used for fragile objects, furniture, etc. The air being loaded with dust is caused to pass through a separator provided with a number of cells for retaining the dust, after which the filtered air is passed through a canvas bag out into the open. The receiving chamber can be made in metal and provided with a disinfecting fluid, thus deodorizing all substances as they enter. The mechanical part of the apparatus, provided with motor and exhauster, can be used as a ventilator.



Electric Photo-Copying Machine.

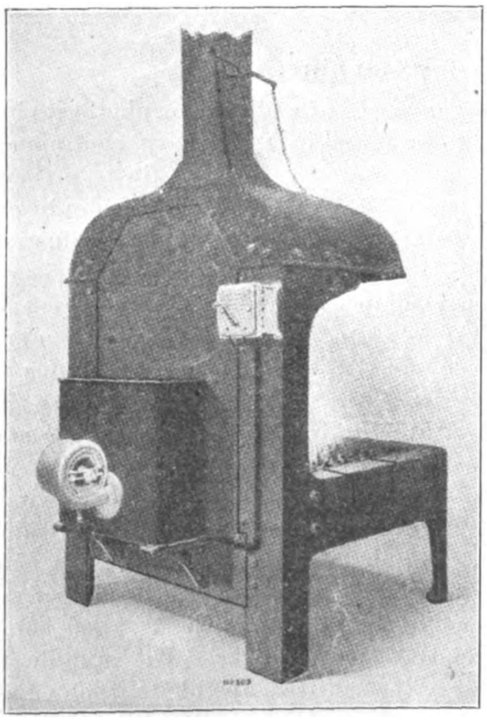
An ozonizer intended for the sterilization of water is shown by the Lahmeyer Company. It is for fixing to the ordinary house lighting mains and water taps. By means of electric current ozone is generated in the ozonizer, and is led to the water tap by means of a thin flexible tube of metallic compound most suitable to resist the chemical action of pure ozone. In this tap there is a diffusing chamber where the ozone is mixed with water, and as the ozone generated is considerably in excess of the amount actually required to sterilize the normal flow of water in any household tap, the sterilization is most effective. One of these ozonizers has been fitted up in the laboratories at Guy's Hospital, London. At Nice, as already known, the municipal authorities are now erecting a large installation for the treatment of the town's supply of water. The output of this installation is to be about 5,280,000 gallons of sterilized water per day for the supply of the whole town.

A useful application of electricity for the purposes of engineering photography is to be found in the Halden continuous photo copying machine. It is a new thing in England, having been only on the market a few months. The illustration will convey a fairly accurate idea of the machine, which is made in single and double form. The latter is the more economical as the one set of arc lamps is arranged in a simple manner to cause the arc light to work on two tracings and prints as they pass gently before it. In working the machine the operator winds on to a loose spindle the tracing, which may be 50 or 100 yards long, or a continuation of tracings lightly joined to each other, the spindle thus filled being replaced in its forks. The spindle to carry the sensitized or photograph paper is run through the roll and in its turn placed in its forks on the table of the machine. The operator draws the end of the tracing on to the end of the photo paper, guiding the two combined to the contact rollers, when he starts the motor which propels the machine. Both substances are fed on to the upper contact roller and the arc lamps are switched on. The tracing with the photo paper behind passes almost imperceptibly between the flat glass plate and the contact rollers. The speed at which Rapid Ferro paper receives the correct exposure is one minute per foot lineal of paper, regardless of width, with 200 voltage. The work is done at table height, the height of the apparatus including the arc lamps being not more than four feet. The motor is of one-eighth horse power and is adjustable to various speeds.



Motor and Blower Combined.

There was also shown for the first time an electric motor and blower combined for blowing smith's fires, furnaces, etc., which is well worthy of mention. The present system of arranging a smith's shop with one large blower for all fires is very inefficient and wasteful of energy, and the small blower and motor have been now made combined in one piece for fitting direct to the tuyeres of each forge. The one casting forms the casing of the blower and the field of the motor. The air propellor is of aluminum, and the weight of the revolving part is very small. The motor is series wound and has carbon brushes. An extension of the blower fits inside the tuyere and carries a valve which prevents the gases from the fire coming back to the blower; this is opened and closed automatically by the air.



Electric Motor and Blower Applied to a Smith's Fire.

◆

LIGHT, HEAT AND POWER PRINCIPLES.—V.

BY NEWTON HARRISON, E. E.

Methods of Distributing Electricity.—The evolution of the incandescent lamp led to further development in methods of distributing electricity for light and power. At the same time the dividing line between the engineering field devoted to direct current and the engineering field devoted to alternating current became more and more eliminated. Electricity is developed at present in two ways:

First—By means of direct current machinery.

Second—By means of alternating current machinery.

The apparatus employed in each case naturally led to a difference in the methods of distributing the electricity. In the first case, the continuous current is generated and led directly, through the medium of large conductors, to the street, and past thousands of homes and business establishments. In the second place, the electricity generated at a dangerously high pressure is led, by means of small conductors, to points where its distribution is required; and then, by means of transformers, lowered in pressure and led into places where it is to be used.

Distinguishing Differences—Taking the point of view of labor and expense, the situation presented is that of one system, using more copper because of a low pressure direct current being employed for incandescent lamps, arc lamps and motors; and the other system, employing a high tension alternating current, which is not distributed directly, but indirectly, by means of transformers to the points where it is to be consumed. These disguishing differences are at present of importance, because the outline of each system in this respect shows the extent of its adaptability to large or small cities. An outline of each system will also serve to show where they may be advantageously combined, as already suggested, and as they are combined in large central stations.

Outline of the Alternating and Direct Current Systems.—The alternating current system in outline makes use of the following elements to compose the system as a whole:

ALTERNATING CURRENT SYSTEM.

1—The alternator. 2—The exciter. 3—The switchboard. 4—The transformer. 5—The system of distribution. 6—The motors, arc lamp and incandescent lamp.

The reference made to the lamps and motors is in order to present the idea that the system can operate motors if their construction is adapted to the character of the alternating current employed. In this respect the additional items must be added, entitled: First, single phase; second, two-phase, and third, three-phase currents. Each of these currents will operate arc and incandescent lamps, and each can operate motors, provided they are constructed so as to fall within the classification of single, two or three-phase motors.

The direct current system is simpler, in the respect at least that the electricity is not transformed after leaving the central station as regards its pressure. Its elements are as follows:

DIRECT CURRENT SYSTEM.

1—The generator. 2—The switchboard. 3—The system of distribution. 4—The motors, arc lamps and incandescent lamps.

It is evident that the absence of any sub-generator to the dynamo in use, and the absence of transformers, is illustrative of the directness of this system. The conductors practically lead directly from the generator to the consumer via the station and street or overhead wires. In the alternating current system, however, the metallic connection between the station and the consumer ends in the primary or—in this case—the high tension coil of the transformer. At this point the inductive relation begins. The consumer's light and power in this system is derived from a coil simply placed in juxtaposition to the other coil whose extremities connect with the station. There is no metallic connection, no direct electrical connection, but merely an inductive relation supplied between the station and the consumer. In showing these two systems of supplying electricity for light and power from a central station, or a station deriving its power from a larger and more distant station; the characteristics of the alternating will appear, emphasizing the discontinuity metallically, but likewise indicating the continuity with the direct current. The reason for this difference is found in the peculiarities of the two currents. The energy of one can be transmitted readily through a large enough conductor and used as it is transmitted. The energy of the other is transmitted through a smaller sized wire, and is either used at the beginning or end of the circuit, or both, to create inductive action. This causes a condition to exist, of a system composed of a series of separate parts, at the points of metallic separation, associated, however, only inductively. This condition is imposed by the fact that the transformation of the pressure of an alternating current up or down can only be caused practically by inductive action.

Position of Central Station.—The central station must be regarded as a reservoir of electricity distributing the energy to the different customers in the neighborhood. The position of this reservoir therefore, with regard to these self-same customers must be such that a minimum of power is wasted, and the least possible amount of copper utilized. In other words, the lines are not laid carelessly or purposely, but are placed in certain locations with regard to the central source of energy so as to attain these objects.

RIVER

One Central Station with Auxiliary Substation Employed for Electric Light and Power.

If, for instance, a series of city blocks are taken into account forming a square shaped area, it is quite evident that the best position for the central station is that formed by the intersection of two diagonals from the corners of the square. On the other hand, if the city area is circular, the center of it would be approximately the best position for the station. The presumption is, in each of these, or in other cases that the demand for lighting is nearly uniform. By this is meant, that either the list of customers is one which gives a uniform distribution, or other indications lead to the conclusion that the lighting will eventually become uniformly distributed. In this case, whether the current used be alternating or direct, the best possible position for the central station is one in which it is about the same average distance from certain distinct groups of consumers. If the customers were grouped in a circular area, the center of this area for the central station, would place the customers in a series of concentric bands. Or, if the area of current distribution is square, the position of the central station is likewise determined as that approaching the center of the listed customers.

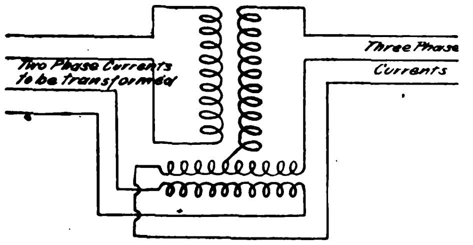
The Central Station in Practice.—A large city may not present a case where it is economical to feed all conductors from one center. For this reason a series of centers are inaugurated, from which conductors lead to a given area of city blocks. A number of central stations would then be employed to supply the entire city with electricity; but it will be divided up in this case into sections or divisions, and each division will be treated as an independent case.

Another method is that of having a single great station situated in a given position, either at the center, or preferably at the edge of the city line. From this point, conductors are run to substations situated where central stations proper would otherwise be necessary. The sub-stations thus constitute centers of distribution for a given area. They could be entitled distributing stations as regards their actual function. The idea in any case is to reduce the annual power loss in the distribution, and to minimize the primary outlay for copper. Another governing reason is the cost of real estate. A position near the water, such that coal barges can anchor directly under the station and deliver their coal, is preferable to any. By this means the fuel cost, as far as the delivery is concerned, is held in check, and the water required for condensers, etc., readily obtained.

An examination of the conditions of lighting of any great metropolis discloses the fact that the elements employed are practically the same as would be installed for actual power transmission. The original energy may be developed at a pressure far too high for use, without the aid of converters. The advantage being that the development of a high pressure alternating current means a limitation not only of the copper, but of the power which would otherwise be wasted as well.

General Use of Polyphase Currents.—The simple alternating current is not sufficient for the purposes required of it. A motor built to operate on a single phase circuit must either be started up by outside power, or its starting device is not one that shows other than an effort to meet this condition with certain complications.

A single phase motor does not possess the widely recognized advantages of the two or three-phase motors. For this reason, it was to have been expected, that the polyphase current systems would ultimately represent the highest standards of power generation, transmission and distribution. That they would predominate in all cases where large enterprises of this kind were projected is also a logical conclusion borne out by practical experience. At present the central stations in large cities are of a composite type, particularly New York. Both the polyphase system, and that termed the direct current, are used in conjunction with other. It is evident that as far as the economical handling of the electrical energy is concerned the polyphase occupies the most prominent position. The distribution is made in the shape of direct current. Not only does electric lighting gain great advantages by its use, in the way of copper, real estate for stations, and therefore the avoidance of an unusually heavy investment, but the system of power transmission is entirely dependent upon this form of electrical energy. The ease of transformation of three-phase into two-phase, or *vice versa*, and the readiness and economy with which either of these is turned into direct current, has been the means of simplifying and making practical the handling of large quantities of power at distant points. A diagrammatic sketch of the transformation of two into three-phase, is added for reference.



The Transformation of Two into Three-phase Currents.

THE NAVAL ELECTRICIAN.*

The idea of becoming a naval electrician probably appeals to a good many lads who have some knowledge of electricity, and fancy the prospect of going out into the world on board a man-of-war; to not a few of these the uniform is, perhaps, an attraction, with its peaked cap and brass-buttons savoring of the full-blown naval officer.

Far be it from us in any way to discourage a feeling of pride in the uniform of either of the services, for it is surely a pardonable form of vanity that brings out such qualities as are needful "for the sake of the cloth."

However, it is but fair to point out to those who may only have seen the shore-going side of life, that there is a good deal beyond the peaked cap and the high-sounding title of electrician, which does not appear on the surface.

To begin with the title electrician is, perhaps, a little misleading, for it would seem to imply that the holder of it is responsible for, and generally in charge of, the electrical plant on board ship. One might be led to infer that his opinion on electrical matters would have considerable weight, and that he was, in fact, more or less of a "boss" in his own particular line.

Now, as a matter of fact, the electrician is not an officer at all in the naval acceptance of the word; he is a mechanic pure and simple, supposed to have special knowledge of the sort of work required in the adjustment and repair of electrical instruments.

The electrical engineer of the ship is the torpedo officer, whether he be a warrant officer or a lieutenant appointed for those duties; his right hand man is the torpedo instructor, a man who has entered in the ordinary line and has taken up the torpedo branch in preference to gunnery.

The electrician occupies rather the post of instrument maker, though his actual duties in a great measure depend on his special aptitude for certain kinds of work as observed by the torpedo officer.

As an example, let us take a battleship or large cruiser, and see in what manner the work is generally divided up, and what duties in particular will be likely to come under the care of the electrician. To do this we must endeavor to place ourselves in the position of the torpedo officer, and see what arrangements are best suited for the disposal of the staff under him.

As regards the work that it is his special duty to supervise, it may be divided first of all into two great items—the illumination of the ship and the efficiency of the Whitehead torpedo armament.

His staff will probably consist of two electricians, two torpedo instructors, a few permanent ratings in the torpedo branch—some half dozen or so, and any men that the commander may be able to spare for special work that is in hand and requires what one might call unskilled labor, such as the cleaning of torpedo tubes and such minor odd jobs.

The half dozen or so permanent "hands" would be called the electric light party, and the bulk of them would be employed going round chasing earth leaks, repairing circuits and renewing lamps wherever necessary.

A responsible man must be in the neighborhood of the switchboard, another reliable man should be in charge of the electric light party, a third is required to look after the bells, batteries and telephones.

Now all these men have their own little calls upon the electrician's workshop; they go round and gather up the fragments of misapplied ingenuity which follow in the wake of untutored ambition.

There are switches which have suffered from some burly autocrat who did not realize that the current was broken at the sectional box, galvanometers which have had their faces slapped and turned sulky, other instruments which have displayed a marked antipathy to sea water, and a host of minor fittings with which sea air does not agree. All these things claim the attention of the electrician, and test his skill as an artificer in brass, but they do not, as a rule, require any great technical knowledge. The electrician whose duty it may be to attend to these items has his hands full, and it is always easier to write up the defect book than to write the items off.

But, besides electric work, the torpedoes claim a large amount of the torpedo officer's attention; men must be detailed to look after these, and a specially skilled and neat workman must attend to the gyroscopes, upon which the straight-running of each torpedo depends.

A gyroscope consists essentially of a perfectly-balanced heavy fly-wheel, running on ball bearings.

Now, everyone who has possessed a bicycle knows that it requires a definite amount of force to turn the front wheel when it is set spinning rapidly in the air; it is precisely this force that is made use of in the gyroscope when the little fly-wheel is set revolving, and the resistance to any turning movement is made to act upon valves which control the rudders.

This little instrument, which forms an integral part of each torpedo, is exceedingly sensitive, and at the same time it is of the utmost importance that it should be accurate.

Who better than the electrician with his skill in handling delicate instruments, for the job? So it comes about that electrician No. 2 becomes a specialist in the art of gyroscope adjusting to the exclusion of almost any kind of electrical work whatever.

Now, to the man who has taken up electricity as a study, who has studied the theory of it, and, perhaps, prides himself on his electrical certificates, this may, possibly, be decidedly disappointing; he had, perhaps, visions of wireless telegraphy, and the large field of investigation that this branch of the subject throws open to the inquiring mind; he had pictured himself in charge of a ship's installation with all its ramifications, the ball systems, telephones, telegraphy, lighting, battery work, dynamo and motor work and all varieties of testing; his certificates are a guarantee of his right to an opinion, and his title would seem to invite it, but he finds himself instead tied down to his lathe, making endless terminals and ebonite bases, carrying out routine orders, and consulted in nothing; there is another in the place that he thought to occupy, and he is not even this person's deputy, for there are torpedo instructors whose official certificates entitle them to a higher place.

---

*From the "Electrical Review," London.

It may not always be so—in fact, it is probable that there will be great changes in the new future—but for the present we would point out the advantages of working up through the regular line where it is a case of ambition, for the torpedo instructor becomes eventually a torpedo officer, and, in due course, may even get a commission.

The naval electrician is, however, not at all badly placed when once he realizes his true position; as an instrument maker no one can touch him; he is master of his craft, and as such will earn the confidence of his officer. Once this is established it is not likely to be forgotten, and he will be looked upon as a man of no small importance.

Electricity is more or less of an innovation in the navy, and it is daily growing in importance. The electricians, as a body, must remember that the engineers started in much the same way, only with more prejudice against them; within the last few years recognition of their merits has come to them in rapid strides, and there would seem some liklihood of considerable changes being effected in the electrical branch.

Torpedoes and the electrical plant have little in common; the link was first welded in the adoption of electrically-fired mines, when the torpedo officer was the only individual who was supposed to be sufficiently well acquainted with the fact that electricity can only travel along a metallic circuit, and is held there by the surrounding insulation through which it cannot pass.

In these days of high frequency currents, specific inductive capacity, self-induction, and so forth, he has to know a good deal more, and modify the views of his predecessor considerably; leaving out his executive work, leaving out even his Whitehead torpedoes, he has still quite enough to worry him as an electrical engineer, and the day is probably not far off when, putting aside his other duties, he will assume the latter sobriquet alone.

AN ELECTRIC MINE PUMPING PLANT IN BELGIUM.

BY FRANK C. PERKINS.

One of the most interesting electrical mine drainage installations in Belgium is that at the Concorde Collieries at Jemeype-sur-Meuse. The accompanying illustration, Fig. 1, is an interior view of this mining power plant, and Fig. 2 shows the underground electric pumping plant.

In the mines at Maquets the company has a beam engine which has been in operation since 1878, two electric pumps, working at a depth of 1,330 feet, and an underground steam pump, working at a depth of 680 feet. The electric pumps were originally operated by continuous current motors, but are now driven by alternating current motors of the three-phase type. About a decade ago an electrical pumping plant was installed, consisting of an inclosed motor driving by two sets of gearing a three-throw pump capable of delivering 3,250 gallons per hour to a height of 1,330 feet, the speed of the pump being 31 r.p.m. The current was generated at a pressure of 500 volts by a direct current dynamo of the International type, driven at a speed of 375 r.p.m. by a vertical compound condensing engine of 200 hp. capacity, built by Willans & Robinson. A second electrical pump was installed in the underground plant a year or so later with an electric motor of much larger dimensions than the former, which had not given the best of satisfaction. The motor was also of the inclosed direct current type, but had a lower temperature rise on account of its larger dimensions, and also as it was fitted with water circulation to further aid in cooling. This equipment operated for a number of years successfully, although the first pump which had become generally defective was replaced by a new electric three-throw pump in 1900, and the output of the generating plant was increased by installing a Carels steam engine, directly coupled to a direct current dynamo of 500 volts pressure.

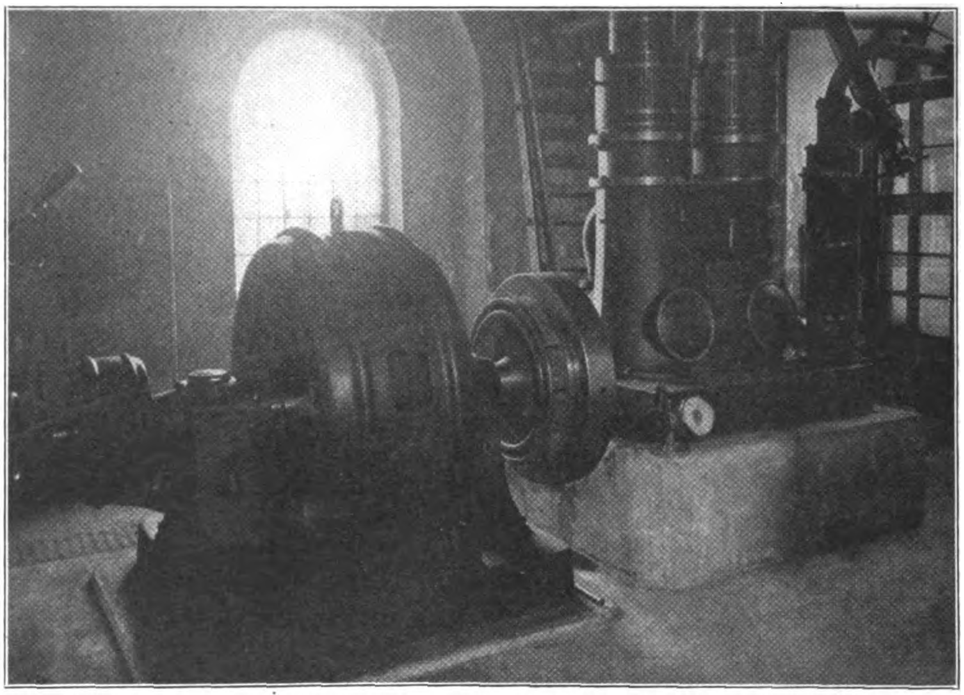


Fig. 1.—200 Hp. Engine and Alternator in Power House of Electrical Mine Pumping Plant.

An entirely new electric installation for mine pumping was under consideration when the beam engine became damaged by an accident and the lower underground pumping room was flooded at a depth of 1,330 feet, the direct current motors being ruined by being submerged in the pump room for about two weeks.

The entire installation was then converted into a three-phase alternating current mine pumping plant by the International Electrical Engineering Company of Liege, Belgium, and a test was made by two professors from the Liege University, showing that an alternating current motor of the three-phase type could be operated under water without damage for a short time. An International three-phase motor was completely immersed in water and operated for a quarter of an hour in this manner when it was placed under seals after being stopped, and remained submerged for a night and a day. It was run for a short time by Professors Gerard and Debast and then removed from the water and allowed to dry for 24 hours, when the motor was found to be in perfect running order and the insulation in good condition. The new plant installed in the Concorde Collieries included a three-phase alternator directly coupled to the Willans & Robinson 200 hp. engine, which has a high pressure cylinder with a diameter of 300 mm. and a low pressure cylinder of 433 mm., the piston stroke measuring 203 mm. The Carels engine was also coupled to a similar alternator having 14 poles and supplying a current having a frequency of 43.8 cycles per second. The Carels engine has a piston stroke of 200 mm., the high pressure cylinder measuring 300 mm. in diameter and the piston measuring 430 mm. in diameter. A steam pressure of 10 atmospheres is used, the condensation being by injection, the water pump from the mine being used for this purpose in a reservoir 30 feet above the condensers.

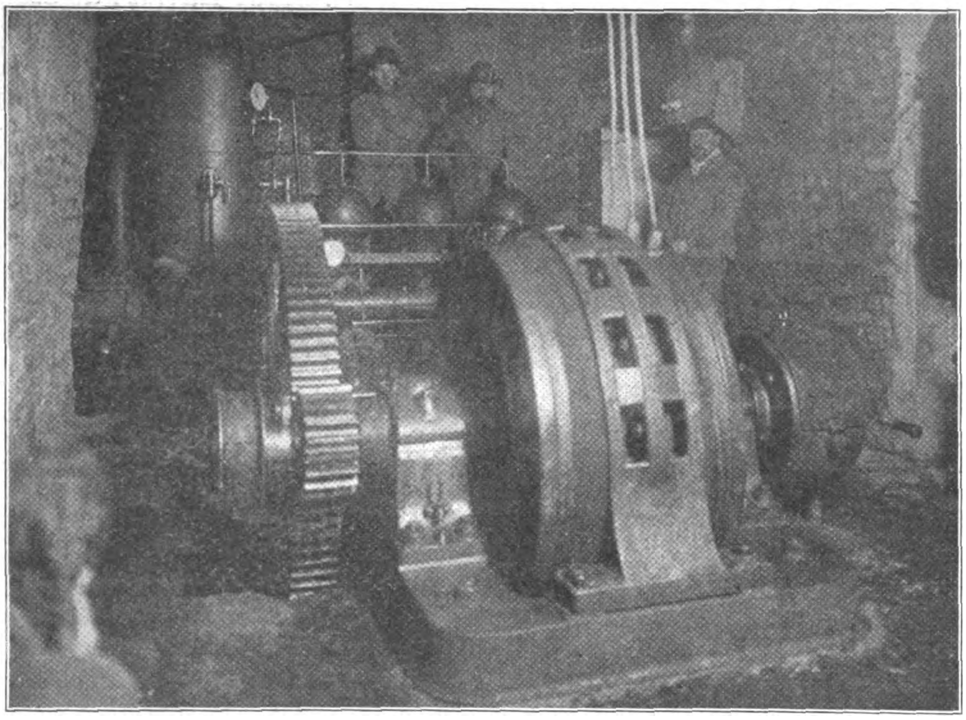

Fig. 2.—Belgian Underground Mine Pumping Plant.

The exciters and their alternators are connected to the switchboard by cables running in conduits. This switchboard consists of three white marble panels, the two end ones being reserved for the generators and the center one for the exciters and the synchronizing circuit. The current passes through the circuit breakers and then through the switches before reaching the feeder cables. The board was designed to make the service simple and sure and to prevent any false operating which might arise through an accident. All the metallic parts carrying current at high tension are placed at the back of the board, which latter is constructed without the use of any combustible material. The frame is of iron and the insulators of porcelain.

The safety fuses are composed of long pieces of silver wire stretched down the center of the porcelain tubes and fixed to removable contacts. By means of these contacts the fuses can be replaced without danger while the generator is running. The switches are operated by means of long metal rods carrying the contact blades by means of insulated pieces. They are of the quick-break type, and the rapidity with which they open together with the distance between the contacts enables the current to be cut off when the machine is running with full load without fear of permanent arcs being produced. The three feeder bars are connected to a three-core armored cable 480 meters in length, which carries the current to the bottom of the pits and thence to the motors. The three conductors, which have each a sectional area of 75 sq. mm., are first covered with vulcanized rubber, afterwards stranded, the whole then covered with two sheetings of lead and finally armored over all with tinned steel wire.

At the depth of 1,330 feet the cable leaves the shaft and is conducted along a gallery to the pump room, where a junction box is placed in a convenient position, and from which run the two cables feeding the pump motors. In each of these circuits a high tension single-phase circuit breaker is fixed of the same type as those at the surface but inclosed in a cast-iron box. This box also contains a switch, which can be controlled from the exterior, and an ammeter, which can be examined through a glass window arranged for that purpose. Each pump is driven by a motor with revolving field of 80 effective horse power at a speed of 420 r.p.m. One electric pump has a speed of 31 r.p.m., and is driven by means of two sets of gearing; the other one has only one set of gearing and a speed of 80 revolutions.

The starting is effected by means of a rheostat with metallic resistances working in oil having inclosed contacts, which are connected with the rotor by means of slip rings in a hermetically inclosed box. They are fitted with an arrangement for putting in short circuit and lifting the brushes.

The motors are especially designed for resisting the hot atmosphere and dampness of the mine and the conductors are protected by waterproof insulation.

SINGLE-PHASE VS. POLYPHASE TRANSMISSION LINES.[*]

BY H. S. WATSON.

In spite of the great success of three-phase alternating systems signs are not wanting that electrical engineering opinion may yet return to the almost discarded single-phase system; in fact, the merits of the latter for large traction schemes are so incontestable as far as the most important part of the problem is concerned—viz., the track work—that when the single-phase motor problem has been fully solved there will, in the opinion of the writer, be no question of using any other system on electric railway schemes of any magnitude.

The advocates of single-phase have not been afraid of conceding to the three-phase system a saving of 25 per cent. in the copper of the transmission lines; and it is this supposed disadvantage of the single-phase system to which I wish to draw attention; not that my view is a new one, as it has often been stated before, but fallacies die hard, and I believe that even to-day many electrical engineers have an implicit faith in the high copper efficiency of three-phase transmission.

This relative copper efficiency, paradoxical though it may seem, depends entirely on the point of view from which the question is looked at. Everyone knows that in any given system for the same efficiency the weight of copper varies as the square of the voltage. In comparing the copper efficiency of a three-phase system with a single-phase system it, therefore, becomes absolutely necessary to decide on the basis of comparison. If we assume that a single-phase system with 10,000 volts between its lines is comparable with a three-phase system having the same voltage between its lines, of course the three-phase system has the lower copper cost for the same efficiency. But is this a fair basis of comparison when an overhead line is in question?

---

[*] From the "Electrician," London.

Consider what is really the condition that governs the two cases. It is that the insulation between any one line and earth shall be the same. This is obviously so since the distance between any two lines should be so great that there is no chance of leakage or breakdown from one line to the other, and therefore the only thing to take into account is the leakage from any conductor to earth. That is to say, the insulators are the determining factor. Let us first, as our basis of comparison, take a three-phase system connected up in star with the center point earthed, having a given voltage, V, between any conductor and earth. The voltage between the phases is $\sqrt{3} \times V$. Let the current flowing in each line be 2C. Then the power which will be transmitted is $(\sqrt{3}V \times 2C)\sqrt{3} = 6VC$, and the amount of copper required in the system for any given efficiency will be proportional to $2C \times 3$ (since there are three lines) $= 6C$.

Now, take the case of a single-phase transmission line. To obtain the same condition—i.e., the same voltage V between any line and earth—we must earth the system at the middle point; then the voltage between the two lines will be 2V. Now the contention is that, if the copper be the same in the two systems, the power transmitted at the same loss will be the same; as the quantity of copper is to be the same as before, it is proportional to 6C; therefore, having only two conductors, the current flowing in each, for the same loss, will be $6C \div 2 = 3C$. The power transmitted will therefore be $2V \times 3C = 6V\ C$, the same as in the case of the three-phase system. In other words an equal power can be transmitted with the same efficiency in the two cases, if the weight of copper is the same. Whether the three-phase system is supplied by star or delta-connected generators of course does not affect the argument; if the star system is used, it is easy enough to connect the center of the system to earth; if the delta system is used, the same effect can be obtained by making an earth connection through choking coils.

It is interesting to note that in America it is found that for extra high tension (40,000 to 50,000 volts) the greatest difficulties to be dealt with are the insulators and the lightning arresters; the potentials to earth, and not those between line and line, are the causes of these troubles.

When such high voltages are employed, whether a three-phase or a single-phase system is used, it will probably be found best to adopt the system of lightning protection recommended by J. Moscicki and W. Waeber, in which each line is connected to earth through a condenser with a choking coil in parallel with it. This method, whether applied to a three-phase or a single-phase system would, of course, insure that the potential of each line was equidistant from earth.

The above arguments lead to the consideration of the question whether, with overhead transmission, it is better to erect a single-phase or a three-phase installation; and it would appear to the writer that there is some point at which the first cost in the two cases is equal. This point will depend on the distance of transmission, and must be determined by the following considerations: On the one hand, the prime cost of single-phase generators is higher than that of three-phase generators. On the other there must be considered the cheaper switchboard, fewer insulators and 33 per cent. less labor required in erection of the overhead bare cable. As regards the running costs, it will hardly be disputed that the handling of the power station will be facilitated by a single-phase equipment; and with regard to outside maintenance, there would be only two lines to look after instead of three.

The evolution of a practical single-phase motor for factory work has been slow, but is now not very far from accomplishment, and several railways are seriously considering the applicability of single-phase working to their lines. It would seem, therefore, that the relative cost of transmission by single-phase, as compared with three-phase, when an overhead line is permissible, should be considered with more attention than it generally receives, and that the misconceptions as to the copper efficiency of the three-phase system, which are undoubtedly widespread, should be rebutted. It is, perhaps, unnecessary to add that the preceding arguments apply, with suitable modifications, to the comparison of single-phase with two-phase or any other polyphase system.

German Electric Road Statistics.

The statistics concerning German electric road lines show that during the 12 months ending October 1, 1904, the towns provided with such services increased by four. The length of route increased by about 60 miles, representing a total of 2,375 miles. The total output of the generating plant, according to the "Electrical Engineer," London, has increased only by about 1½ per cent., while the total output of accumulators on traction load shows a somewhat greater increase, the total accumulator capacity installed amounting to 39,809 kw. In explanation of the small increase in generator output it may be mentioned that the plant of the Hanover street railways has been reduced from 10,063 kw. to 4,555 kw.

WRINKLES.[*]

EDITED BY H. C. ABELL.

The Washing of Waste and Wiping Cloths.

About a year and a half ago we bought an oil press to press the oil out of waste, and after some experimenting we bought a small-sized washing machine, such as is used in a steam laundry, connecting it up with steam and water and running the same by the use of a 3 hp. motor we had on hand. We now wash all of the waste and wiping cloths used by running the machine for about two hours once a week. We use a washing soap called "Takeanap," and some washing soda with it, and make quite a saving over buying new waste. C. E. INMAN, Warren, O.

Installing Apparatus on Second Floor as Protection from Floods.

In planning an alternating current substation in a location subject to possible flooding from a nearby stream due to freshets it was found that a saving of 10 per cent. in the cost of the building could be made by installing all apparatus on the second floor, approximately 12 feet above the street level, thereby saving the waterproofing that would be necessary if apparatus were placed on the lower floor.

LEONARD L. ELDEN.

Single-Phase Commercial and Series and Incandescent Street Lighting from One System.

It became necessary to supply single-phase commercial and series incandescent street lighting service to a small suburban town a number of miles from the substation. The returns possible were so small that it was not profitable to install two wires for each circuit, and therefore three were installed, two of which were for the commercial single-phase service and the third for the street lighting circuit, one of the wires of the commercial circuit being used for the return wire of the street lighting circuit. The only disadvantage to this scheme was the fact that the street lighting circuit was alive during the day, but this proved to do no harm, and, as it was necessary to work the street lines, a switch was installed on a pole in the district supplied, which opened the street lighting wire attached to the commercial circuit, thereby killing the street lighting system and making it safe to work on. Leonard L. Elden.

---

[*] Paper presented before the National Electric Light Association at its 28th convention, held at Denver-Colorado Springs, Col., June 6-11 1905.

Remedy for Blowing of Fuses on Overloaded Transformers.

Two years ago eight 30 kw. transformers were tied into a common secondary supplying the business portion of the town. One night during the peak of the load one transformer blew a fuse, thus throwing the load onto the adjacent transformers; these, in turn, blew their fuses on account of the additional load, and in less than a minute all eight transformers were out of service, leaving the business section of the city in darkness.

The next day circuit-breakers were put in on the secondaries between transformers, and no trouble has since been experienced. To save the drop in copper the various sections were tied together on 75-ampere fuses.

Leonard L. Elden.

Broken Water Pipe—How to Fix Temporarily.

I have found from experience that General Electric splicing gum, with a good covering of Acme friction tape, will hold a broken water pipe until it can be permanently mended.

F. M. Laxton, Atlanta, Ga.

Method of Preventing Destruction of Lead Coverings of Cables at Draw-Bridge Crossings.

A method used to prevent destruction of lead coverings of cables where they enter and leave the water at drawbridge crossings in locations where large quantities of direct current railroad return currents are flowing in approximately the same directions as the cables are laid has been to install a large bare conductor, say 1,000,000 circular mils, in the water across the drawbridge or channel and bond it thoroughly to all the cables on each side of the channel at a point well above the water line of the highest tide. This has entirely obviated the relatively rapid destruction of the lead coverings of lighting and transmission cables from currents of the street railroad company.

Leonard L. Elden.

Thawing Water Pipes.

In thawing frozen water pipes about the plant we have found that a one-inch galvanized-iron pipe is readily thawed by a current of 250 amperes, but a section of 1.5 inch pipe gave us trouble, as it required more current than we could safely supply with the means at hand.

To furnish a conductor of high resistance four No. 10 iron wires were wrapped in a one-sixteenth inch asbestos sheet doubled, bound to the pipe and the latter packed as before. In this case it was convenient to attach one end of the wires to the pipe and use it as a return. We can now thaw the pipe with about 100 amperes. The asbestos is sufficiently good insulation as regards electricity and a sufficiently good conductor as regards heat.

In using this method care must be taken that each wire carries its share of current and that the wires are not overheated; in any case it is wise to watch any combustible material about the pipe.

G. Hartman, St. Gabriel, P. Q.

A NEW GIANT OF THE SEA.

The newest and most complete product of marine architecture, namely, the "Amerika," of the Hamburg-American line, arrived in this port from Hamburg last week.

This new twin-screw ocean liner is a marvel even among the modern giants of the sea. With the exception of her sister ship, the "Kaiserin Auguste Victoria," to be ready for service in May, 1906, the "Amerika" is the largest ship ever built for passenger service. Her construction and equipmemt include many novel features, with regard both to the safety and the luxurious comfort of her passengers. Not only has care been taken to meet every reasonable requirement of the patrons of the new liner, but also to anticipate the whim of the most fastidious traveler; and the effort has produced a craft on which the most timid or squeamish seafarer may brave the terrors of ocean travel with impunity.

This ship has a length of nearly 700 feet over all, a breadth of 74 feet 6 inches and a depth of 53 feet. Her displacement, exceeding that of any other ship in the world, is about 42,000 tons and her gross tonnage about 23,000 tons. Loaded she carries 16,000 tons of cargo, which means that if her full cargo were transferred to freight cars, and these placed end to end, they would cover a distance of 10 miles. She has accommodations for 3,400 passengers and carries a crew of 600, making a total of 4,000, or nearly as many persons as the population of an 18-story skyscraper in New York.

A great novelty introduced in the construction of the "Amerika" is the electric passenger elevator. This is located on the starboard side near the main companionway and serves the five decks of the ship. It is not so many years ago when even buildings in our larger cities were without elevators. But, just as modern progress in mechanical construction has made possible the 30-story building, with its electric elevator, so has similar progress in marine construction brought about like results in this, the latest product of the shipbuilders' art.

Without attempting to enumerate all the novel features of the new ship, a few more may be mentioned. These include a Marconi wireless telegraph apparatus; stateroom telephone service; hydropathic and electric baths and massage, and a thoroughly equipped gymnasium.

It would be of little avail to have made all these provisions for comfort and convenience of passengers, if the more important feature of safety had been given less care. The safety devices on the "Amerika" include the newest and best provided by modern service. Among these is a system for communicating through the water between the ship and the shore. By the use of this system—that of the Sub-Marine Signal Company of Boston—the navigator can find by bell signals the location of lightships and lighthouses regardless of weather conditions. The Stone-Lloyd system for closing the water-tight bulkheads is also in use. By pushing a button on the bridge it is possible in a few seconds to close the water-tight doors of every compartment into which the hull of the ship is divided. Protection against fire, too, is provided by the newest extinguishing system—that of forcing sulphuric acid gas into the threatened premises and smothering the flames.

The "Amerika," while not designed to be a record breaker in speed, is driven by Harland-Wolff quadruple expansion engines of over 15,000 hp., built on the balanced principle. She will make the trip to England and France in about seven days, and that to Hamburg in about eight and a half days.

Overhead Transmission in France.

The new rules as to overhead transmission in France recently appeared in "l'Electrician," Paris. In France continuous current up to 600 volts is counted as "low pressure," so as to include with a comfortable margin all electrically-operated railways. The rules state that single bell insulators or simple oil insulators are not sufficient in the case of high pressure lines and without specifying what contrivance to that end is to be adopted, it is enacted that the wires must be protected from falling across roads. The distance at which wires must be kept from houses or other buildings is one meter. As regards the extra high pressure transmissions which are becoming comparatively common, no attempt is made at present to standardize. It is simply laid down that anything above 10,000 volts will be dealt with specially. On the whole the rules are short and simple enough, but it does not follow that they are all the contractor will have to comply with. In general the local authority has power to impose such additional restrictions as may be suited to the circumstances of the case.

American Institute of Electrical Engineers.

The next regular meeting of the Institute will be held at the Assembly Room of the New York Edison Company, 44 West 27th street, on Friday, October 27, at 8:15 P.M. The subject of the meeting will be "Lightning and Lightning Protective Apparatus." The following papers will be read and discussed:

"Performance of Lightning-Arresters on Transmission Lines," by N. J. Neall.

"Some Experiences With Lightning Protective Apparatus," by Julian C. Smith.

"Note on Lightning-Arresters on Italian High Tension Transmission Lines," by Philip Torchio.

Another Municipal Ownership Tip.

The council at Topeka, Kan., proposes to sell its municipal electric lighting plant. Councilman Frank B. Sims, of that city, had the following to say on the subject: "It seems to me that the plant is a mighty big expense to the city considering the benefit we get out of it. We will have to enlarge the plant to give adequate service to the city and that will cost probably $15,000. Then we will have to pay about $5,000 more for new lamps. If we can dispose of this plant to some corporation that will do the city lighting at a reasonable figure it seems to me that it would be a good business proposition."

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until November 7 for furnishing Eastern Navy Yards with the following electrical material: Schedule 190, conduit, Gonda prisms; schedule 191, motor, electric wire, cable, Grimshaw tape, fuses, etc. Blank proposals and detailed information can be obtained upon application to the Bureau at Washington or to the Navy Pay Office in New York.

Good Book Against Municipal Ownership.

We have received from Mr. W. C. L. Eglin, secretary of the National Electric Light Association, Mr. M. J. Francisco's new book, entitled "The Business of Municipalities and Private Corporations Compared," and find it a very convincing argument against municipal ownership of electric lighting plants. Mr. Francisco's former book, "Municipalities vs. Private Corporations," of which the new book is practically a revision and enlargement, was found by many of the members of the National Electric Light Association to be of very great benefit when combating the municipal ownership idea in their respective cities and towns. Mr. Francisco's statements are always carefully verified, and ought to carry the strongest conviction that up to the present time city ownership of electric lighting plants has proved in almost every instance a gigantic failure, and is likely to do so wherever undertaken.

Ticonderoga.

The little hamlet of Ticonderoga, New York State, has two occasions for distinction, one being of war and the other of peace. A fort was built there in the 18th century and was later captured by General Ethan Allen, in behalf of the American army. The occasion of the capture was a thrilling episode in the war of the Revolution long, long ago. The remains of the fort are still in sight and this year, 1905, between 18,000 and 20,000 tourists stopped there and paid the old fort grounds a visit. The United States Government should buy the site and keep the walls from further disintegration.

The other occasion of distinction is the Dixon Ticonderoga flake graphite mines. These have become even more celebrated than the old fort. Outside of these two things Ticonderoga would be in dense obscurity.

An American mining engineer recently made a report, saying among other things: "The Dixon mining plant at Ticonderoga is equipped with the most modern and improved machinery and apparatus for mining, concentrating and refining graphite." Another writer says: "The only deposit of graphite that has been worked systematically for a period of years, is the Dixon graphite plant at Ticonderoga." Another writes: "The Dixon plant at Ticonderoga has outclassed others and stands first, and produces flakes of such purity as to command the best prices."

There was a celebration one day in August, 1905, at Ticonderoga on the fort grounds, at which Mr. George B. Bascom, a resident of Ticonderoga and a well-known member of the Dixon mining family, was the chief orator. His recapitulation of history, character delinations and his reminiscence of old times in Ticonderoga were pronounced fine by those who heard. Indeed, they had to be, for it is one of the Dixon maxims that its men must do well whatever they do or quit. Bascom's speech was called AA1. Hurrah for Ticonderoga, renowned in history and by the Dixon graphite mines.

THE TELEPHONE WORLD.

Cut in Telephone Rates.

Officials of the New York & New Jersey Telephone Company have announced that beginning on November 1 next the rate from pay stations in Jersey City and Hoboken to other stations, public and private, will be reduced from 10 to 5 cents for each call.

Asked if the fact that the Coast Line Telephone Company, which was incorporated in New Jersey last June, inspired the New York & New Jersey Company in making the reduction in rates, an official of the company said the reduction was made to increase the business of the company in Jersey City and Hoboken. "The 5 cent rate," he said, "had been in operation in Bayonne and Union Hill for several months, and the increased business in these places warranted giving the residents of Jersey City and Hoboken a cheaper rate."

William F. Midlige, of Jersey City, a director in the Coast Line Telephone Company, said that, as counsel for the company, he will in a few days apply to the Jersey City authorities for franchises, and designate streets through which the Coast Line Company intends planting poles and stringing wires.

"We have already obtained 15,000 subscribers in Hudson and Essex Counties," said Mr. Midlige, "and I am sure that our success has frightened the officials of the New York & New Jersey Telephone Company into reducing their rates to retain their subscribers. I expect reductions will also be made in Newark."

The fight of the Independent telephone companies to enter Cincinnati, which has been in the courts for nearly two years, will come up for final hearing before the Supreme Court of Ohio November 1. The action grew out of the refusal of the city council to grant a franchise providing for the building of conduits, erecting poles and stringing wires in Cincinnati to the Cincinnati Telephone Company, the Interstate Telephone Company, the Queen City Telephone Company and the Fitzsimmons Telephone Company.

W. W. Tracy, ex-owner of the Hale Telephone Exchange, for the last two years manager of the system in Clarence, Mo., has sold his interest to W. E. Naylor, of Hagers Grove. Mr. Tracy has purchased the Shelbina telephone exchange and will take possession January 1.

The United Frederick & Clarke Telephone Company of Frederick County, Va., has the following officers: J. H. Funkhouser, president; P. M. Funkhouser, secretary and treasurer; J. S. Haldeman, stockholder. The capital stock is $1,000. Its objects and purposes are to maintain and operate a telephone line.

A special meeting of the Southern New England Telephone Company will he held November 1 in New Haven, Conn., to accept a legislative amendment to its charter which permits the company to issue $10,000,000 capital instead of $5,000,000 as at present.

The La Grange & Waldrick Telephone Company of Oldenburg, Tex., capitalized at $1,000, has lately been incorporated by H. Amberg, Louis Voelkel, Charles France and others.

Large Increase in Telephone Bonds.

According to the Census Bureau report on telephones and telegraphs for 1902, the total amount of telephone bonds then outstanding was $73,981,361. Up to that date while the total volume of telephone securities amounted to a par value of $348,031,059, the bonded indebtedness amounted to only 21 per cent. of this.

It was the policy of the early Bell financing to issue stock rather than bonds wherever possible with the result that several large Bell companies had no bonded debt or very little. Out of the total, the Bell companies had outstanding in 1902, $306,627,501 capital stock, and $65,673,272 bonds.

Since 1902 development has been very rapid, and one of the most remarkable changes has been the modification in the character of securities. It is probably safe to say that the bonds of the principal telephone companies now outstanding aggregate $150,000,000. The supply has doubled in three years, and 1902 stood at the end of a decade whose closing years saw an active telephone development.

This change appears to be largely due to the advent of the Independent forces.

Bell Service Will be Investigated.

At a recent meeting of the Griffin, Ga., city council, the Southern Bell Telephone & Telegraph Company was roundly scored by several members on account of the alleged obsolete 'phones and miserable service the company' giving to subscribers. A committee was appointed to investigate the matter thoroughly and report at the next meeting of the council, when some drastic measures may be taken to remedy the trouble.

The work of combining the Farmers' Mutual Telephone Company of Wellsboro, Pa., and the Citizens' Mutual Telephone Company of Mansfield, Pa., has lately been completed. The two companies have long worked in conjunction with each other, and now operate over 2,000 telephones in all directions in the counties of Tioga, Potter and Bradford.

Prof. H. A. Kinney, of Woodbine, Ia., president of the Southwestern Iowa Telephone Association, has called a special meeting of that association to convene at Council Bluffs on Saturday, October 28, for the purpose of discussing the clearing house movement for the Independent companies in the association.

The Cortland, N. Y., Home Telephone Company has begun the building of the line extending out to Groton avenue toward Groton City, a distance of about six miles. A large number of farmers will be accommodated by the new line.

The London "Economist" estimates that the British Government's telegraph system last year showed a deficit of $5,800,000 while the postal system earned a surplus of $52,800,000 for the same period.

The Odessa, N. Y., Telephone Company has been incorporated with the following directors: L. T. Couch, Wlliam Lattin and C. L. Frost, of Odessa.

Talk of Improving Service.

Representatives of the Mutual Telephone Company of Des Moines, Ia., lately met with the East Des Moines Commercial League, to discuss the advisability of improving the telephone service in that part of the city. Considerable benefit could be derived, it was believed, from the securing of a better service on the east side of the river, and the members of the Commercial League expressed their willingness to offer every encouragement toward the installation of a large number of 'phones and the general improvement of east side service.

Owing to the recent business growth of East Des Moines, it is expected that the Mutual Company will make a special effort to increase the number of subscribers by putting in a better service.

John I. Sabin, former president of the Chicago Telephone Company, died October 10 in San Francisco, Cal., after an illness of one week. Mr. Sabin, at the time of his death, was manager of the Pacific States Telephone Company. He was best known in Chicago as the promoter of the party line and nickel-in-the-slot telephone system, in connection with which he installed the multiple exchange system.

A new corporation has been organized by the citizens of Attica, N. Y., to be known as the Attica Home Telephone Company, for the purpose of erecting a telephone system and change there and connecting the same with the several towns and villages of Wyoming and Genesee counties and with the several Independent toll line telephone companies. George T. Loomis, Clarence H. Beane, W. A. Joiner, Elon P. Spink, Hugh Miller, Carlton D. Wing and Henry B. Flach are the directors. The capital stock of the company is $10,000.

A new telephone system, according to a recent report from Muskogee, I. T., is now being installed in the United States Indian Agency. It is called the intercommunication system. The Indian agent by merely pressing a button opposite the number desired acts as his own operator and can call up any office in the agency without appealing to "central.' Each office has a similar mechanical device, which gives the head of each department the same privilege of calling up any other office. Indian Agent Kelsey estimates that this system will save the Government hundreds of dollars in the time employed each year.

The Missouri & Kansas Telephone Company lately turned $1,773 into the Kansas City, Mo., treasury for the use of the streets during the last three months for its conduit system:

The work of stringing the cables for the Inter-Ocean Telephone Company in Danville, N. Y., is progressing rapidly and the system will soon be in operation.

The Commerce, Tex., Telephone Company has amended its charter, increasing its capital stock from from $5,000 to $10,000.

With a capital stock of $1,000, the Milan, Ind., Telephone Company has been chartered

GENERAL ELECTRICAL NEWS.

LIGHTING.

Avalon, N. J.—The borough council has employed an expert to formulate plans and estimates for the installation of an electric light plant here.

Byhalia, Miss.—This place is to have electric lights and waterworks. The new enterprise is under the management of R. D. Berry.

Dallas, Tex.—The mayor and city attorney are engaged in drawing up a contract with the Dallas Electric Company for furnishing this city with electric lights for a period of three years in accordance with the action taken by the council about the middle of the year. This contract will provide for the free lighting of the streets during the State Fair.

Fort Payne, Ala.—The manager of the telephone exchange has been working for some time to get a system of electric lights for this place and has about succeeded in his efforts. He has secured a sufficient number of customers to make the enterprise a success.

Greencastle, Pa.—Contractor Jacob Shank has started the erection of the power house for the electric light plant.

Greenville, Me.—The Greenville Light & Power Company is constructing a new and larger electric plant a short distance south of Wilson Pond, about three miles past here.

Hyattsville, Md.—W. P. Magruder, W. S. Holton, J. W. Aman and others have organized a company with a capital stock of $20,000 to erect and operate an electric light and ice plant.

Iron River, Mich.—The matter of issuing $30,000 of bonds for municipal improvement purposes will be voted on at a special election to be held here to-day. Of the amount it is proposed to raise, $20,000 is for the establishment of an electric light plant.

Mayo, Fla.—The town council has granted a franchise to Clarence H. Ellis and others for the right to put in a system of waterworks and an electric light and power plant.

Monroe, Mich.—George Gilsky, of Kalamazoo, is now manager of the municipal lighting plant. The city is to be entirely rewired and put on a meter system.

Nashville, Ill.—K. H. Steinhasuer has purchased the Nashville electric light plant from the present owners.

New Brunswick, N. J.—A call has been published for a meeting of New Brunswick business men to consider the feasibility of the establishment of an electric municipal lighting plant. The call is signed by 28 of the leading business and professional men of the city.

Ocilla, Ga.—This city has let a contract to J. B. McCrary, of Senoia, for the construction of waterworks and an electric light plant.

Paducah, Ky.—John S. Blecker, of Messrs. Stone & Webster, Boston, Mass., has secured the franchise to operate an electric light and power plant here.

Philipsburg, Pa.—The arc lights throughout the town are being replaced with new ones, made necessary by the new system being introduced by the Electric Light Company.

Pikeville, Ky.—The Pikeville Electric Light Company has been incorporated with a capital stock of $50,000 to operate an electric light plant.

Plains, Pa.—The people here are to have their own electric light plant in the near future.

Springdale, Ark.—This city has granted a franchise for an electric light plant to Spencer Owen, of Belgrade, Neb.

Streator, Ill.—This city is talking of putting in a public electric light plant.

STREET RAILWAYS.

Birmingham, Ala.—J. M. Dewberry and others have secured a franchise to build and operate electric car lines in Jefferson County

Bloomsburg, Pa.—It is now proposed to extend the Bloomsburg & Danville trolley line as far as Northumberland. For further information address W. S. Pascott.

Chambersburg, Pa.—The directors of the Chambersburg, Greencastle & Waynesboro Electric Railway Company recently went over the line on which the proposed road is to be built.

Davis, I. T.—J. C. Root, chief engineer in Kansas City, has been here surveying for the electric line to Turner Falls.

Davenport, Ia.—According to information given out by John Farson, of Oak Park, who is president of Farson, Leach & Co., of Chicago, this city is to have an electric interurban line, connecting with Chicago.

Eau Claire, Wis.—Three local capitalists, O. H. Ingram, B. A. Buffinton and John S. Owen, with others, have bought outright the street railway system of this city and Chippewa Falls, including the Eau Claire electric lighting plant.

Jonesboro, Ark.—Grading and other work will begin at once on the Jonesboro & Nettleton trolley line.

Los Angeles, Cal.—This city is soon to have another electric railway line, linking it with the Santa Monica beach and thence along the coast of Ventura County. Mrs. Rindge is at the head of the project.

Louisville, Ky.—The Louisville & Indianapolis Traction Company, incorporated with a capital of $10,000, by John R. Schindell, of Cincinnati, and Charles Redman, has been formed for the purpose of looking over the field with a view of building a line north from Jeffersonville.

Marshalltown, Ia.—Prominent business men of this city, Waterloo, Grundy Center and Newton have incorporated the Union Traction Company, the purpose of which is to build an electric line from Waterloo to Newton, through this city. The company is capitalized at $100,000, and will be promoted by H. L. Smith, of Indianapolis.

Morgantown, W. Va.—The Morgantown & Dunkard Valley Railroad Company will build a power house.

Pasadena, Cal.—Linda Vista, one of this city's suburbs, may soon have an electric railway.

Paterson, N. J.—It has been decided to begin at once the work of constructing the proposed new electric railroad from this city to New York and at the first meeting of the directors of the New York & New Jersey Rapid Transit Railway Company engineers submitted plans. They estimate that the cost of building the road will be about $8,000,000.

Philadelphia, Pa.—Pennsylvania Railroad officials, after an exhaustive investigation, have become satisfied that electricity is the coming motive power and have decided to electrify one of its two lines between Camden and Atlantic City, N. J.

Salem, Ore.—It may be announced definitely and authoritatively now that there will be an electric railroad built connecting this city with Portland.

Shelbyville, Ky.—It is announced that actual work of construction on the Shelbyville & Ohio River Electric Railroad, which is to run from here through Newcastle, Eminence and to Carrollton and Milton, will begin in a few days, bonds amounting to $1,000,000 having been floated to finance the construction.

Washington, D. C.—A. H. Semms, in behalf of himself and several capitalists associated with him, has obtained permission from the district commissioners to advertise the fact that they intend to offer a bill in Congress at the next session for the charter of a new electric railroad in the District of Columbia.

Waxahachie, Tex.—The city council has adopted an ordinance granting a franchise over the streets of this city for an interurban electric railway, to run from here to Dallas and on to Ennis.

POWER PLANTS.

Knoxville, Tenn.—The Oliver Company of this city has been awarded the contract to build the dam and power plant for the Tennessee River Power Company, about 30 miles below Chattanooga. The contract price is $2,000,000, or slightly in excess of that amount. Work on the monster project is to begin at once and will be rushed to completion.

Lockport, N. Y.—W. B. Skinner, of New York City, has been here working on the transmission line to Buffalo from this city for the Niagara, Lockport & Ontario Power Company. The line will run from Lockport to Pendleton along the Buffalo & Lockport tracks, thence to Getzville, then through the town of Amherst to Williamsville and thence to Buffalo.

BIDS WANTED.

Brooklyn, N. Y.—On November 1 bids for the contract for insulating the consolidated power plant will be received by Civil Engineer Hollyday. The plant will be installed in building No. 41 at the Navy Yard and the motive power will consist of compressed air, electricity and steam.

Washington, D. C.—The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until November 14 for furnishing the torpedo station at Newport, R. I., with the following: Schedule 188, conductor cable, testing magnets, copper wire, dry battery cells, keyboards for observation mines, firing battery and junction boxes. On November 21 the Bureau will open bids for furnishing Western Navy Yards with the following: Schedule 178, electrical fittings; schedule 179, motors. The Bureau will also receive sealed bids until November 28 for furnishing the Mare Island, Cal., Navy Yard with an auxiliary fire alarm system. The schedule number is 187. Prospective bidders can obtain blank proposals and detailed information of the above by applying to the Bureau at Washington.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅜@16⅝c.; Lake 16⅜@16⅝c.; casting, 16⅛@16⅜c.

It is stated that about $2,000,000 New Haven, Conn., capital is invested in the Boston suburban lighting field.

The Automatic Electric Company of Chicago has declared the regular quarterly dividend of 2 per cent., payable November 1.

C. A. Coffin, president of the General Electric Company, has been elected a director of the American Locomotive Company.

The Northern Texas Traction Company has declared the regular quarterly dividend of 75 cents a share, payable November 1.

The Old Colony Street Railway Company of Boston has declared an annual dividend of 2 per cent. on its outstanding capital stock of $7,312,400.

The directors of the United Traction Company of Albany, N. Y., have declared the regular quarterly dividend of 1¼ per cent., payable November 1.

The City of Chicago has been granted permission to submit records in the street railway cases which are set for hearing by the U. S. Supreme Court on January 2.

The directors of the Cambridge (Mass.) Electric Light Company have declared a regular quarterly dividend of 2½ per cent., payable November 1.

Inside interests say that the Brooklyn Rapid Transit system will surely show gross earnings of $18,000,000 next year, and that such gross earnings would warrant the beginning of dividends.

The decrease in the earnings of the Manhattan Elevated Railway Company of New York, as shown in the annual report, was 7 per cent. as compared with the previous year. The management had expected a decrease of 20 per cent.

The Chicago Edison Company has sold electric current equal to 7,000 horse power on long contract to the Chicago City Railway Company. During the next two years the Edison Company plans to expend $4,000,000 in improvements.

Walter H. Whiteside, president of the Allis-Chalmers Company, denies emphatically that there is any truth in the rumors of contemplated absorption by the General Electric Company. Still there are others who believe "there's something doing."

From the maps filed by the Hudson Street Railway Company, which was recently incorporated, it proposes practically to parallel the trolley lines of the Public Service Corporation of New Jersey, now in operation throughout Hudson County.

There was a report in Wall Street Monday that the New York City Railway Company had sold $1,000,000 worth of mortgaged real estate to put the money in improvements, but had been forced to deposit the money with the trust company acting as trustee. This was authoritatively denied.

The New York State Gas and Electricity Commission has received application from the Kings County Electric Light & Power Company of Brooklyn for permission to increase its capital stock from $5,000,000 to $10,000,000 for the purpose of improving its plant. A hearing was set for November 17 at the commission's New York office.

EDITORIAL NOTES.

Cities Doing Their Own Electric Lighting.

One way of looking at municipal ownership is to look at the record it has already made. Another is to examine the principles upon which it is supposed to rest as a working theory. If the general public were sufficiently well acquainted with both it is unlikely that so many would express opinions indicative of sheer ignorance on the subject. At its best, it is a question which cannot be settled by a public vote, for the self-evident reason that the voters, unless people of the highest acumen, are merely guessing. So grave a matter as saddling a community with the legal and financial responsibility of an industry is no different from that of buying a shoe factory, to make shoes for the public when they walk the streets. It is not very different from that of running a large bakery, because everybody must eat bread. It is, in certain respects, the thin edge of the wedge of socialism, which, beginning with one thing, will not and cannot end theoretically until it has embraced all things representing public needs.

It is, of course, only one item that is to be considered—the lighting of the city streets and public buildings. Yet how complicated a business so simple an item represents. If the present corporations doing electric lighting have had to invest millions of dollars and spend years of time in experiments, which not only yielded the present efficiency of operation, but what is more important, perhaps, yielded the present experience in this great industry, what will the city do to conduct its business properly? Is it reasonable to suppose that it can succeed in such an enterprise, and prosper to the same extent, without going through the same money-burning experiences? It is widely admitted that experience costs money, and whether it is in shoemaking or breadmaking, there is that something to be learned to make it a success. But this is not all; there is also a large investment to be considered.

Juggling facts and figures will not remove the conclusion that where a large investment is made it must yield a reasonable profit. Such a sum, when put into operation, must produce what is expected of it. If it partly represents machinery, its earnings must include depreciation. Wear and tear are important items of expense, which must be considered as well as other things.

It is, of course, impossible to take up this subject from a clerical point of view without referring to the necessary items constituting it. But the rough outlines of the proposition can be noted, and then such facts as are pertinent to municipal ownership with respect to its present results in American practice.

To begin with, one of the fundamental principles of progress in the industries is that competition is the first and only stimulating cause. Remove competition and every step forward becomes an effort. In electric lighting, competition and scientific advance have been the moving forces. Under the rule of municipal ownership no contrasts can be made, either as regards machinery or system employed, that would not be regarded as a political move to invite a new and unnecessary expense. The political feature, therefore, would condemn it from this standpoint, as well as that of its opportunity to provide positions of political preferment. Thus, the destruction of competition and the creation of a new source of political revenue are the features militating against it.

The immense cost is the next point; not only as an expenditure of money, but as a form of investment that represents a constant depreciation. The public may think that electric lighting is a very profitable business, but like any other large business, its profits are the result of enormously heavy investments and years of persistent effort. Laying down a million dollars' worth of copper underground means not only this but a great labor bill in addition. The companies using subways have done it, and anyone else must do the same. But even in duplicating the moves of corporations the city does not necessarily save itself.

The Detroit plant is spoken of by Mr. M. J. Francisco, who has thoroughly investigated this subject, as a case of "gross underestimates of cost and incorrect figures for depreciation." In Massachusetts and Connecticut a law had to be passed forcing managers of electric light plants to estimate depreciation at 5 per cent. In other words, the reports of municipal plants from all over the country, almost without exception, show an exaggerated tendency in this direction. Underestimates of cost and depreciation are to-day the real foundations for a belief that a city can do its own electric lighting cheaper than it can buy electricity. How many instances arise in private business where the temptation to save in a certain direction is recognized by the far-seeing and shrewder class as a delusion and a snare. The manager of the municipal plant in Detroit will not admit the rate of depreciation fixed by law in other communities as being true in their case. Therefore they present reports leaving out important items of expense to prove success. Not only is this true of Detroit, but of other towns and cities trying the experiment. But even admitting this to be true, what will be the cost of this lighting when the entire plant must be thrown out to make way for the newest and best in the line? What will such an item be when compared with the saving previously calculated?

* * *

Electric Surges in Power Stations. Electric surges in power stations arise through the sudden rupture of a circuit, through the fuse blowing, or the switch being opened too suddenly, which controls a large quota of power. To those versed in the technics of resonance it is well known that a certain relationship between the self-induction, capacity and resistance of a circuit, will create oscillations and high pressures of a character dangerous or not, depending upon the influence they have upon the insulation. The sudden breaking of a power-carrying circuit, whose capacity and inductance express such a relationship that the ohmic resistance offers a free path, may mean the development of a pressure sufficient to burst through the regular insulating covering at some point or other, and start a destructive arc between two cables.

But electric surges are caused directly by what may be termed the sputtering of an arc in a circuit. They make and break the circuit at some important point and develop the class of surges spoken of—tremendous tidal waves of electricity which roll back and forth in the circuits and station, wrecking machinery and burning out cables.

Resonance is allied in certain respects to these surges. More, however, because they are fundamentally alike, than because they can be otherwise identified. In circuits with resonance, should such a misfortune occur, the self-induction and capacity do not appear. But the current will develop a pressure due to this condition that may break down the insulation and cause such surgings to occur, through the arc formed at the point of rupture, as to threaten the entire system. Opening every main switch in such an instance is the only means of providing an immediate relief from the dangers of widespread destruction.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

There are at present over 6,000 accident suits pending against the Metropolitan Street Railway Company of New York, and the company has determined to fight to a finish a gang of "habitual fake-accident suit bringers."

The formal opening of New York City's lighting plant under the Williamsburg Bridge took place Monday afternoon. Mayor McClellan turned the switch which will light up the bridge and the plaza at the Brooklyn end of the structure. The new plant will furnish power for the electric pumps in use at the stations on either end of the bridge. It includes four generators. The cost of the plant, which will burn refuse from the streets, was approximately $60,000.

A cable dispatch from Munich, Germany, says that Prof. Korn, a leading electrical inventor of that city, claimed in a lecture before the Eletrotechnical Association that the problem of transmitting photographs by telegraph had been solved in principle, and it was now possible to transmit a photograph or sketch six inches square in from ten to twenty minutes. This was done over a telegraph line between Munich and Nuremberg, but was equally practicable over 5,000 miles. The photograph to be transmitted is placed in a transparent glass cylinder which revolves slowly, at the same time moving from right to left. A ray of electric light is thrown upon the cylinder and lens, and when the ray reaches the interior it is brighter or darker, according to the coloring of that particular part of the photograph through which it passes. Inside the cylinder is some selenium, which transmits an electrical current in proportion to the intensity of the light brought to bear upon it. This selenium is connected with a wire over which the photograph is transmitted.

An organization known as the "Open Shop" Electrical Contractors' Association of Boston and vicinity has been formed in that city for the purpose of fighting the electrical workers' union.

The Fort Wayne & Wabash Valley (Ind.) Traction Company is offering to sell power to farmers within a certain distance of its lines for operating machinery. This experiment is being watched closely by power companies all over the country.

The "Lancet," a well-known weekly paper of London, says it has "discovered" that the atmosphere of the Metropolitan Underground Railway of that city is charged with ozone, created by the multiple electric discharges which take place on the live rail, and adds "that it would have been considered a bold seer who a few years ago had prophesied that the time was coming when not only would the output of evil gases on the railway be stopped, but that they would be replaced by inodorous and ozonized atmosphere."

London, England, is now able to call up Rome, Italy, on the telephone. The two cities are 1,100 miles apart.

Electricity is to be put to a novel test by the Department of Agriculture at Washington, D. C. A laboratory is being fitted in the division of pathology for the purpose of conducting experiments in the growing of plants by the aid of an electrical appliance. The experiments are based on the theory that the growth of vegetable matter, which ceases at sundown, will continue through the night if proper artificial light is supplied to stimulate the natural developing power of the plants.

ONE VS. TWO DYNAMOS FOR A THREE-WIRE SYSTEM.

BY W. H. WAKEMAN.

Fig. 1 illustrates a right-hand dynamo, viewed from the end of shaft on which the commutator is located. When standing at this end and noting the armature as it revolves it turns in the direction traveled by the hands of a clock, as indicated by the arrow.

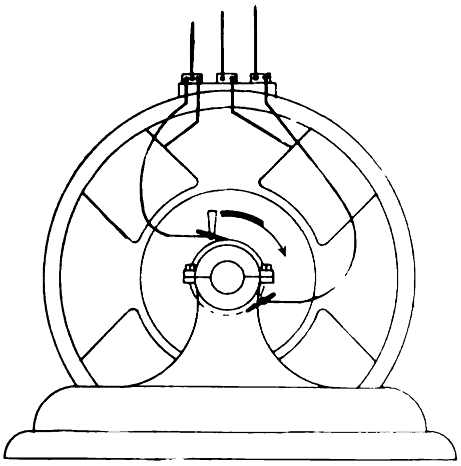

FIG. 1.

Fig. 2 is a left-hand dynamo, and it will be noted that the armature revolves in the opposite direction from the preceding. In other words, a right-hand dynamo revolves clock-wise, while a left-hand one turns anti-clock-wise. In both cases the observer stands at the commutator end of shaft.

Several years ago a dynamo was purchased for my plant and when it arrived I found that it was a right-hand machine, but owing to local conditions it was necessary to use a left-hand type.

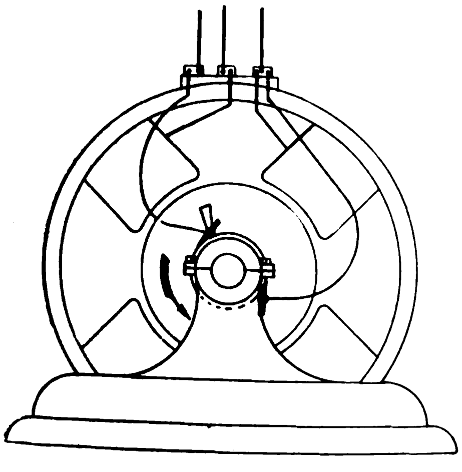

FIG. 2.

As it was fitted with carbon brushes it was possible to run it in either direction without making any permanant change whatever, but the brushes would not look natural nor run to the best advantage because the commutator bars would be running "against the brushes." The meaning of this expression may be explained as follows: These brushes were set at an angle, as shown in both of the illustrations, and when the armatures turn, as indicated by the arrows, they run "from the brushes," but if they turned in the opposite direction they would be revolving "against the brushes."

In my case the brush holders were taken off and turned so as to hold the brushes in the opposite direction.

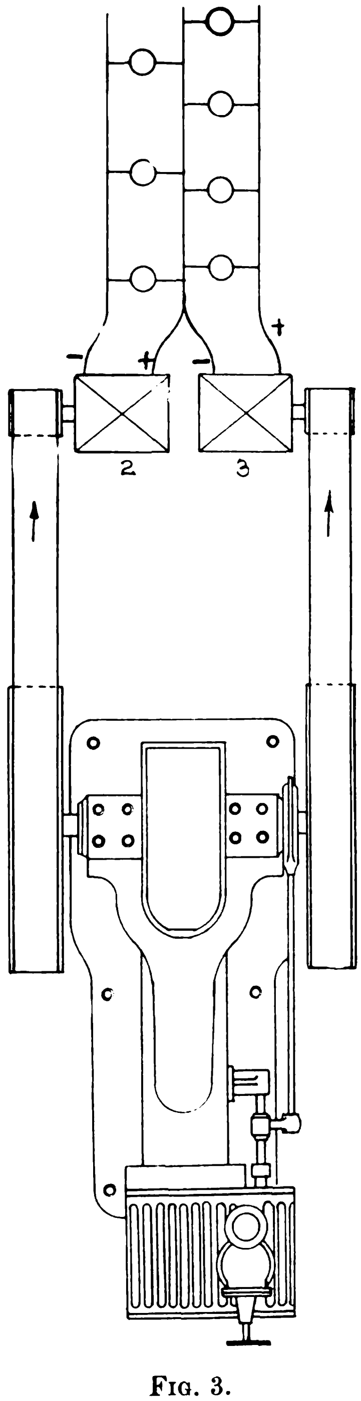

FIG. 3.

Careful consideration of these facts shows that the only essential difference between a right and a left-hand dynamo is that they revolve in opposite directions.

The case is different with a steam engine, as the frame is either made or used different for a right than for a left-hand machine. When you stand at the cylinder head and look towards the crank, if the fly-wheel is on the right hand side it is a right-hand engine, but if located at the left it constitutes a left-hand machine. Some engine builders adopt a different design of frame for each kind, while others simply use them different as they are either right or left-hand, according to which side is uppermost. Of course this does not apply to a center crank engine in which both sides are alike.

Where a three-wire system is to be installed it is customary to use two dynamos, as illustrated in Fig. 3. These are driven by a center crank engine of suitable size using a fly-wheel on each side. Arrows on the belts indicate the direction in which the tops of both belts are traveling.

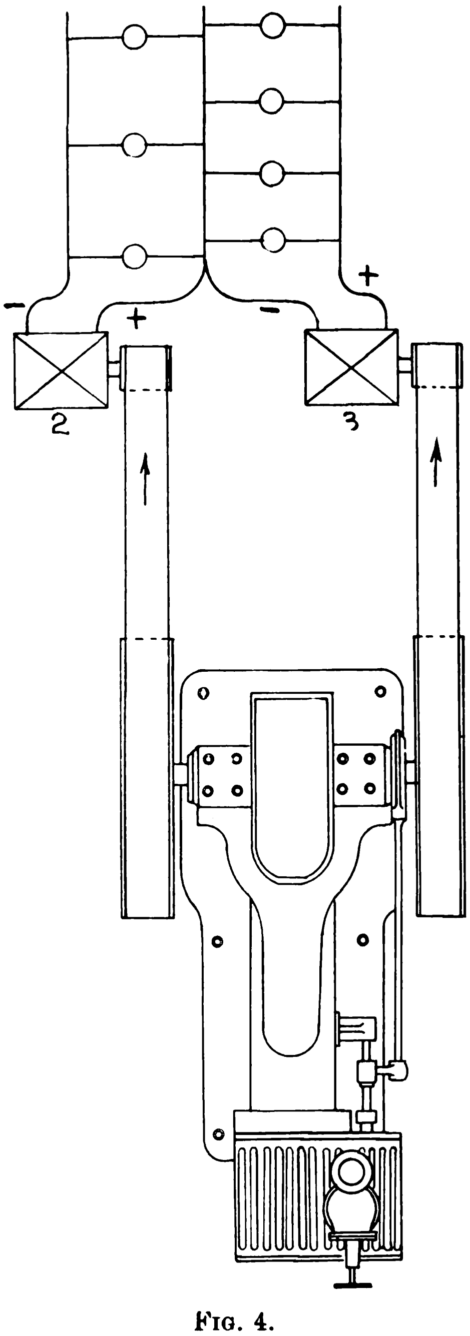

FIG. 4.

In this case 2 is a right and 3 a left-hand dynamo, and as both are driven by the same engine they will run at the same speed, as long as both belts are in good condition for service.

In some cases it may be desirable to arrange the machinery as shown in Fig. 4.

The arrows indicate the direction of rotation as before, but now both 2 and 3 are left-hand dynamos. In both cases more lamps are on one side of the system than on the other, in order to show that it is not balanced, therefore the middle wire returns a small amount of current to the dynamo 3.

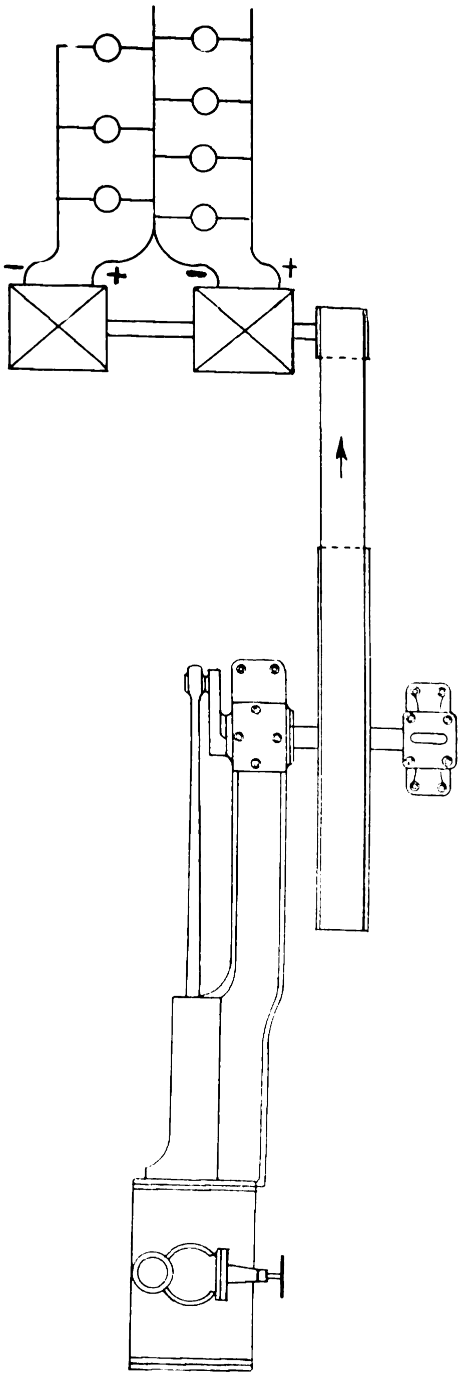

Fig. 5.

Inasmuch as it is desirable in some cases and necessary in others to drive two dynamos at equal speed, why not locate them both on one shaft, as shown in Fig. 5, and use a better type of engine with one fly-wheel and one belt? The wiring system may be balanced or not, according to requirements, with equally good results. As the armatures are rigidly connected they must operate alike whether the belt slips or holds perfectly.

Passing on from this arrangement to Fig. 6 we have one dynamo supplying current to a three-wire system, making a very simple plant from which good results may be expected. While such an arrangement may not be commonly used there is no good reason for calling it impractical, as a careful consideration of the illustrations will plainly show.

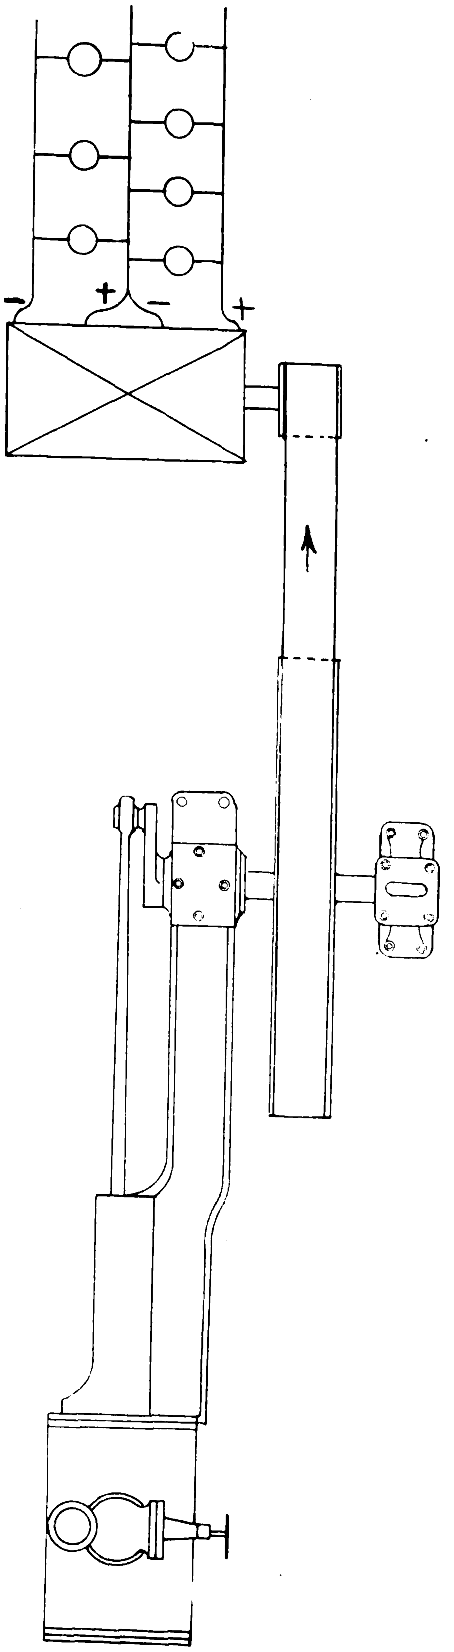

Fig. 6.

Fig. 7 is an elevation of a dynamo designed to generate electricity at two different potentials, thus showing that it is quite possible to devise and execute almost any plan relating to the generation and use of this most subtile and elusive means for retransmitting power. In fact it is more dangerous to state that any desired result cannot be secured with it than to claim the possibility of doing unheard of things, because enough is known by true scientists to make a great many things possible that have not yet been demonstrated in a practical way, and very few electricians are willing to say that we fully understand electricity at the present time.

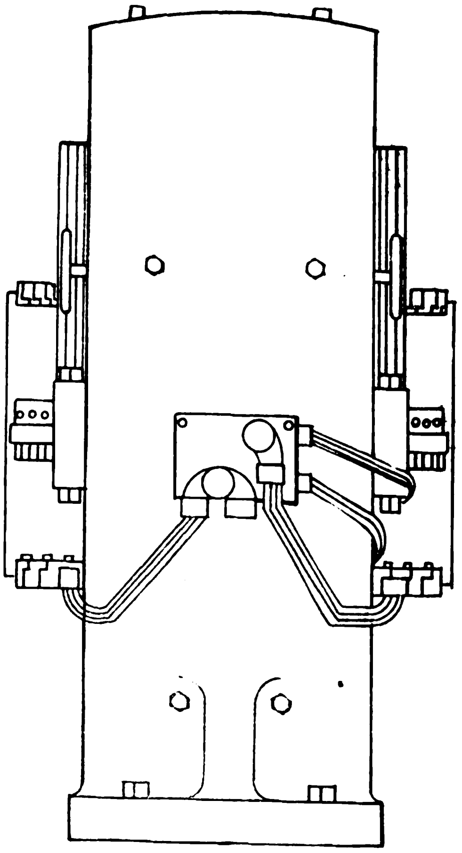

Fig. 7

Rash enthusiasts have prophesied some things that are not yet in evidence, and may never be, but who shall decide which particular thing can never be accomplished after reviewing the progress made during the past ten years?

DOMESTIC ELECTRIC LIGHTING.*

BY JAMES SWINBURNE, M.I.E.E.

On October 6 Mr. James Swinburne delivered an interesting lecture at the Electrical Exhibition, Olympia, London, on the "Lighting of Houses by Electricity," of which the following is an abstract. The lecturer mainly confined himself to a description of the various types of electric lamp and the advantages of the use of electric light in comparison with other methods of illumination.

After mentioning the early work of

---

*From the "Electrical Engineer," London.

Sawyer and Mann, Edison, Maxim and Swan, the lecturer pointed out that the carbon incandescent lamp is to-day practically identical with the lamp suggested in 1836 and successfully made in 1880. The improvements made in these lamps are really improvements in detail of manufacture and standardizing, which have fortunately rendered lamps much cheaper. Important improvements have been made in the method of blowing the bulbs of the lamps. In the early days bulbs were blown by hand; since then, however, the Germans have invented a method of blowing lamps by machinery, in a manner practically identical with that used in making bottles. The exhaustion of the lamps is now generally performed by the aid of a mechanical pump, although the vacuum obtained in this manner is not so good as that found in the earlier lamps. The method of "flashing" filaments invented by Maxim, but generally ascribed to Sawyer, has rendered it possible to obtain lamps which are practically uniform.

Before proceeding to describe the more modern form of electric incandescent lamps, Mr. Swinburne gave an interesting discussion on the relative cheapness of electric light and gas light. In the early days, when the luminous gas flame was used, electricity supplied at the cost of 3d. per unit would have been equal to gas supplied at 2s. per 1,000 cubic feet. This estimate ignores the cost of lamps. At the present day the use of mantles has very much cheapened the cost of gas light. Gas companies say that gas is about 30 times as cheap as electric light, but Mr. Swinburne calculated that the cost of gas was about nine times as cheap as electric light. This, however, is only one side of the question. If cheapness were the only consideration, it would be best to light a house up by providing a large fire in the middle of each room; but, of course, the fumes from the fire would do so much damage to the house that this method would be quite impracticable. The fumes from gas, although not so obnoxious as those from a fire without a chimney, are nevertheless very damaging; a house lighted by gas needs redecorating every four years, while with electric light it would not need redecorating more than once in six years. If you take a house in London and use electric light, and thus render it possible to redecorate it every six instead of every four years, the economy in redecorating will just counterbalance the extra cost of the electric light. In addition, the injury done to leather-bound books, and the extra cost for servants necessitated by the tarnishing of plate, when gas is used, need to be considered. Taking everything into consideration, the electric light would be cheaper than gas for lighting purposes, even if the gas companies would supply their gas for nothing. Mr. Swinburne referred to the fact that light is obtained more economically if the carbon-filament lamp is "over-run," but over-running means a shorter life for the lamp. Most householders run their lamps at too low an efficiency, and also for too long a time. In many cases lamps are still used in houses after they have become so blackened that a large percentage of the light emitted by the filament is absorbed.

Whithin the last few years several improved forms of incandescent lamps have been put on the market. The first of these was the Nernst lamp. In this lamp zirconia is used as the basis of the conductor to be heated by the electric current; its high melting point renders it possible to raise the conductor to a much higher temperature, and therefore to obtain light which is both more economical and more like sunlight. The worst thing about these lamps is that they give a good deal of trouble. When switched on they do not light up at once, since a current has to be sent through a heating coil in order to raise the temperature of the glower to the point when it becomes conducting before the electric current can pass through the glower. This is sometimes very annoying. For instance, a man goes down to his wine cellar where a Nernst lamp is in use; he turns on the switch and nothing happens, when he probably says something and lights a match, gets what he wants and goes away. Afterwards the lamp lights up and burns until someone again visits the cellar. On going into a dark room you will probably have to wait a quarter or half a minute before you can get a light. In the latest types of Nernst lamps small carbon-filament lamps are provided, which become luminous when the Nernst lamp is switched on, and when the Nernst lamp lights up the subsidiary lamps are switched out automatically.

One of the latest forms of electric incandescent lamp is the tantalum lamp. Tantalum is a metal which is not in general very well known. It is nearly or quite as hard as the diamond, and rather stronger than steel. The German firm of Siemens & Halske have succeeded in shaping this metal into very fine filaments and making these into lamps. The high melting point of tantalum renders it possible to raise the filament to a much higher temperature than would be practicable in the case of carbon filaments, and thus greater economy is effected. In addition, the resistance of tantalum increases with the temperature, while the resistance of carbon remains stationary, and under certain circumstances decreases with the rise of temperature, with the result that an accidental rise of pressure that would destroy a carbon filament has no harmful effect on a tantalum filament.

Were it not for the high price of tantalum lamps, carbon-filament lamps would no longer have a chance against their latest rival, but when a carbon-filament lamp can be obtained for a few pence people are loth to pay three, four or five shillings for a tantalum lamp, however great its advantages may be.

The osmium lamp was invented by Auer von Welsbach, the inventor of the gas mantle. Osmium is about as rare as tantalum and about as difficult to work. The osmium lamp is a very promising lamp, indeed, but the difficulty is to obtain a filament long enough and thin enough to possess a sufficiently high resistance for the ordinary pressure at which electricity is supplied. However, lamps have been made to withstand a pressure of 110 volts, and two of these may be coupled in series across 220-volt mains. The osmium lamp has the further advantage that very efficient lamps can be made from it to run at very low pressures, even below 50 volts. Portable osmium lamps lighted by means of a secondary battery have been supplied by the Electrical Power Storage Company; these should be very popular, as they can be turned on at an instant's notice wherever they happen to be wanted.

The Cooper Hewitt lamp utilizes the light emitted when an electric current passes through mercury vapor. In its original form it was unsuitable for domestic lighting, since the color of the light emitted is something between green and blue, and would render the most beautiful lady's complexion hideous. It is, however, excellent for use in drawing offices, and it is being used with great success in photography. It has a very high efficiency—that is, it dissipates very little power in proportion to the light which it emits. Mr. Bastian has invented an improved form of mercury lamp specially arranged for domestic lighting; a carbon-filament lamp is run at so low a pressure that it only emits red light, and this combined with the blue and green light from the incandescent mercury vapor forms a very good light indeed. This lamp brings the cost of electric light down to that required in the case of gas, without taking into consideration the deleterious effects of the latter.

LIGHT, HEAT AND POWER PRINCIPLES.—VI.

BY NEWTON HARRISON, E. E.

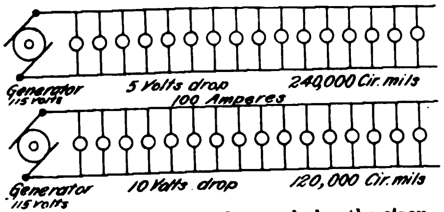
Distribution by Wire.—The direct and alternating current are combined in all large schemes for the transmission and distribution of electrical energy. The reason why a distinction is made between the two processes is because one is, as its name implies, merely distribution. For this reason the machinery employed is not the same as that used in transmission. The other being transmission calls for a system which will give flexibility, efficiency and economy in installation. Both the two and three wire systems of wiring may be utilized, although direct and alternating current respectively are employed—largely direct for the two and three-wire, and generally alternating for the two-wire system only. The direct current system of lighting is one whose distribution takes in the two and three-wire; the calculations of wire sizes being based upon the following simple rule:

Size of wire in circular mils = amperes × feet of wire × 12 ÷ volts drop. For instance, a line carrying 100 amperes with 5 volts drop through 1,000 feet of wire, would require a size of wire equal to 100 × 1,000 × 12 ÷ 5 = 240,000 circular mils. For one-half the drop in volts the size of wire in circular mils is doubled. For one-quarter the drop, the size of wire in circular mils is quadrupled as follows:

TABLE SHOWING THE CHANGE IN CIRCULAR MILS WITH CHANGE IN DROP.

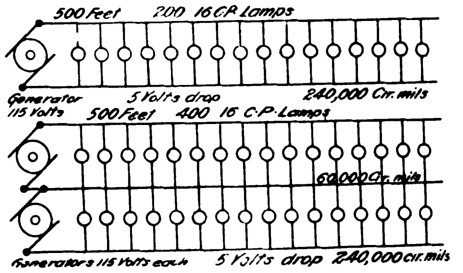
Amperes.	Volts drop.	Length of wire.	Size of wire necessary in circular mils.
100	5	1,000 ft.	240,000
100	2.5	“ “	480,000
100	1.25	“ “	960,000
100	10.00	“ “	120,000

The last line of figures, showing the halving of the size with a 10 volt drop, is given for the purpose of showing how flexible a matter the quantity of copper used may be, with respect to the drop.



Effect of doubling the drop to halve the circular mils.

A Two and Three-Wire System Contras‘ed.—The purpose in using three-wire instead of only two, is for the advantage gained in the amount of copper employed, and the better development of an electric light system so based. It has been shown that in a simple two-wire system the amount of copper is entirely dependent upon the degree of loss sustained. The more willing the proprietors of a plant are to sustain a loss in power, in distribution, or in transmission, the less correspondingly is the amount of copper required. But in all such instances, if the saving in copper is ten, twenty or even fifty thousand dollars, while the cost of the wasted power is, in the aggregate, after a few years have passed, an equal amount, then the saving and the cost are equal, and a new period is reached, where the loss through wasted power brings no compensation. Economy practiced in this direction, is therefore a failure in electric light and power work. But in a three-wire system, the drop can be regulated just as well as in a two-wire system, subject to the option of the designer of the circuit. A three-wire system carrying the same amount of energy as the two-wire can do a greater amount of lighting with less copper in proportion. For instance, in a two-wire system with a 5 per cent. drop as specified, on the basis of ½ ampere per 16 cp. lamp, the 100 amperes would light 200 lamps in a straight bank. But the size of wire would be 240,000 circular mils for the 1,000 feet of wire. On the other hand, if the 100 amperes are sent through a three-wire system, as illustrated, the result would be the lighting of 400 lamps with only the addition of a single wire to the circuit. This single wire in the middle need not have the cross-section of the others. It can be a wire of one-quarter the size, if some reasonable guarantee is given that the lamps are equally distributed on each side of the neutral wire. On this basis, the circular mils of the two-wire system are exceeded only to the extent of the copper in the neutral wire. The drop need not be greater, although double the voltage is used. By the same rule, in estimating sizes of wire, the circular mils equal 100 × 1,000 × 12 ÷ 5 = 240,000 for the two outside wires. The fact that 1,000 feet of wire are employed, is proof that the run is only 500 feet in length. But the 5 volts drop is now divided up between two lamps, and amounts to only 2½ volts apiece. In other words, the 100 amperes and double the pressure, when sent through a three-wire system lighting 400 lamps of ½ ampere apiece, can do this lighting with the same drop in volts between the terminals. It is now carrying double the load, with the addition of a 500 foot wire of 60,000 circular mils. The middle wire only takes up the difference in current between one-half of the lamps on one side and the other. Its size may be even smaller than that recommended, when a perfect circuit balance is established.

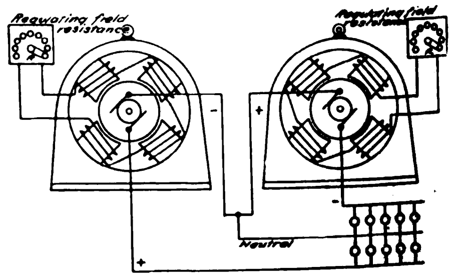


Comparison of two and three-wire system, with equal current in each, but double the lamps in the three-wire.

TABLE SHOWING THE CIRCULAR MILS OF A THREE-WIRE SYSTEM.

Lamps.	Amperes.	Volts drop	Length of wire.	Size of wire in circular mils, including one-half the neutral wire.
400	100	5	1,000 ft.	240,000 + 30,000 = 270,000
400	100	10	1,000 ft.	120,000 + 15,000 = 135,000
400	100	2.5	1,000 ft.	480,000 + 60,000 = 540,000
400	100	1.25	1,000 ft.	960,000 + 120,000 = 080,000

In each case one-quarter of the circular mils of the outer wire were taken as the size of the neutral, and one-half added to give the final figures in the last columns.



The three-wire system with generator field regulation - direct current.

Considering the fact that 400 lamps can be lit, it will be readily perceived that the increase in copper is not great enough to make the difference in wire sizes a matter of much consequence. The system in use for direct and for alternating current is illustrated with respect to the generator connections in one case and the transformer connections in the other.

The Power Factor.—In single-phase systems, or in fact any system using an alternating current, the energy sent in does not necessarily appear in its full value. The illustrations showing the three-wire direct and alternating current systems differ in this respect: that in direct current the total watts are equal to the product of the volts and amperes. In the alternating current the watts are equal to the volts × amperes multiplied by a determining power factor. The fact that the circuit may develop inductive action, and thereby accentuate the conditions through which the volts and amperes do not entirely co-operate, has been the reason why it must be considered. It is the cosine of an angle, or a measure of the degree to which the co-operation is lacking between the volts and amperes. Its importance in power calculations confined to alternating currents is such that they are not comprehensible unless defined according to the imits it imposes. The following explanations will clear the way for conclusions relating to the elements of pressure, current and the extent to which they cooperate.

Angle of Lag.—That which is called self-induction causes the current to lag behind the electromotive force. By this s meant, that although the electromotive orce of the current passing into the circuit is operating upon the said circuit, it cannot instantaneously cause a current to flow. An interval of time elapses which is greater or less, according to the degree to which the opposing influence of self-induction exercises its influence. The meaning of self-induction, as a physical fact, apart from the symbol L by which it is generally represented, is obtained by a consideration of the fact that lines of force surround the circuit or leave it, when a current enters or eaves.

Self-Induction.—The self-induction developed in the circuit is therefore measurable by the lines of force embracing it, and the time they take to either surround or leave it. In certain respects, when a current of electricity flows through a circuit it is equivalent to that circuit being plunged into a magnetic field in such a manner as to produce electromotive force. The fact that the entering current is temporarily checked is due to the opposing electromotive force of self-induction. The conditions are similar to those which appear when a wheel is set into motion and then stopped. Inertia must be overcome to start the wheel, and it must also be overcome to stop the wheel. So in the same sense every electric current develops an electrical inertia to the entering current, and likewise develops an electrical inertia when the current reaches its exit. Though called self-induction it is quite evident that the entering current must meet and overcome an opposing or counter electromotive force. It is also evident that a retreating current cannot be checked instantaneously. These two phenomena are characteristic of all currents, and may be illustrated as described, by reference to a fly-wheel started and stopped, in comparison with a circuit being embraced and disengaged by lines of force.

Lines of Force Surrounding a Circuit.—As long as lines of force are increasing around a circuit, the circuit will continue to develop EMF., but when the circuit is broken, or the current stopped the lines of force are disengaged. This phenomenon is accompanied by the development of another EMF. In other words, to make this fact more evident, when the current is entering the circuit the opposing EMF. of self-induction lets the current in only in a gradual manner comparatively. While only a fraction of a second elapses altogether, the reaction of the circuit takes time to subside, and in subsiding permits the EMF. trying to send a current through to perform its office. Thus the lag of the current behind the EMF. is an element of time though mathematically represented as an angle. The angle is readily explained by reference to a two-pole dynamo, or the two adjacent poles of an alternator.

Meaning of Angle of Lag.—In a two-pole dynamo, the circumference represents 360 degs. A conductor will pass through 180 degs. in passing each pole and one-half of the interpolar space between the pole pieces. If an alternating current is generated by this machine, then the conductor generating EMF. will have moved a slight distance before the current in the armature circuit responds. This interval of time corresponds to the angle through which the conductor moves. In the two adjacent poles of an alternator, the same condition of affairs exists, except that the arc embraced by the two poles is giving a valuation of 360 degs.

The angle of lag is therefore a period of time which elapses before the current flows, and is represented by an angle forming a distinct percentage of the assumed 360 degs. subtended by the pole pieces. For instance, if the alternator is four-poled, then a pair of poles representing on this basis 360 degs. would actually subtend only 180 degs. A six-pole alternator would mean only 120 degs. for two adjacent poles; but according to this standard, they would also represent 360 degs. from the beginning of the EMF. wave to the end of its complete reversal. This idea is represented in a series of alternators of 4, 6 and 8 poles with special reference to the angle of lag. The conditions would imply an equal amount of self-induction in each case, so that the angle of lag is equal throughout. In such a case, although the angle of rotation varies in the case of a 4, 6 or 8 pole machine, the angle of lag does not vary if the peripheral speeds are alike.

◆

NOTE ON LIGHTNING ARRESTERS ON ITALIAN HIGH-TENSION TRANSMISSION LINES.[*]

BY PHILIP TORCHIO.

During a recent trip abroad the writer inspected several high-tension transmission lines in Italy, and found that American lightning arresters with choke coils are quite generally used at the ends of the lines. In addition, Siemens horn arresters are sometimes installed at the ends of the line and at intervals at poles along the line.

The protection furnished by these devices, however, is not considered sufficient, on account of their inability to protect the line and the machines under all conditions of lightning discharges and surges, or even static disturbances caused by load fluctuations in the ordinary operation of the system. Transmission engineers have found it necessary to supplement the ordinary lightning arresters with some other protection, and to that end a variety of devices has been developed on different installations. Among these the so-called "series lightning arrester" of Gola and the "water resistance static discharger" call for special attention.

It is claimed by Gola that the shortcomings of the ordinary lightning arresters are due to some deficiency in the choke coils employed and not to any deficiency in the lightning arresters themselves, their function being only to discharge the line. To overcome the shortcomings of such choke coils Gola devised an apparatus in the shape of a large shell, consisting of a choke coil and a number of large cast-iron diaphragms and shells connected in series by means of small copper conductors, the whole being placed in series on the line to perform the functions of a choke coil, and also to introduce an abrupt and great change in the section, material, and shape of the line conductors leading to the station apparatus. The device is illustrated in Fig. 1. In proximity to the sharp-edged ends of the shell are located corresponding airgap, horn-shaped lightning dischargers which are connected, through a resistance to ground, either directly here or in series with ordinary lightning arresters, according to the requirements demanded by the line voltage. The functions of the supplementary lightning arresters is to assist the main air-gap in rupturing the arc after the lightning discharge has taken place. It is claimed that while this device will allow the main line current to pass undisturbed, it will so obstruct the passage of lightning or static discharge currents as to cause them to be reflected at this point and pass to ground via the dischargers previously mentioned. This obstruction is claimed to be due to several effects of discontinuity of the circuit, in so far as the "homogeneous circuit of the line conductors of approximately constant section and of the same material (generally copper), always in a diamagnetic medium (air or insulating material), is suddenly interrupted by the introduction of several lengths of conductors of magnetic material of section and surface enormously greater, joined one to another by lengths of copper conductors again of small section, but placed in a magnetic medium, the whole with sudden changes of direction and section."

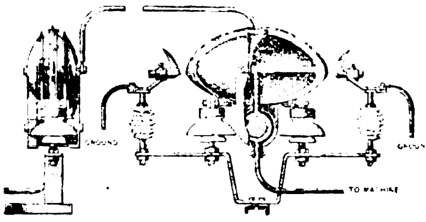

FIG. 1.

Gola, in the publication above referred to, makes several interesting comparisons between hydraulic and electrical laws, and by analogy attempts to explain the operation of the series arrester. The device has been used in many places in Italy for the last two or three years. In many cases it has proved to be most effective, while in other cases the results have been indifferent.

The "water resistance static discharger" of Friese and others is connected at each end of the line, one discharger between each conductor and ground, thereby forming a permanent continuous path to ground for a small fraction of the main line current. A general feeling prevails that this grounding will eliminate a great many troubles from lightning and surges on the line. Several ways of grounding the line are in use in Italy, but the one at the Morbegno station of the Valtellina three-phase railway may be considered as representative of the water resistance type of grounding device. The device, which is shown in Fig. 2, is mounted on an iron frame outside the station. It consists of grounded feed and discharge water pipes supplying the necessary water to three pairs of glass tubes, each pair being joined at the middle by a metallic union to which are brought the grounding connections from the line conductor; the grounding is made through the two water tubes in parallel. The current to ground in this system, operating at 20,000 volts (11,000 volts to ground) is 0.2 ampere from each line wire to ground. The superintendent of the station was hopeful of the success of the device.

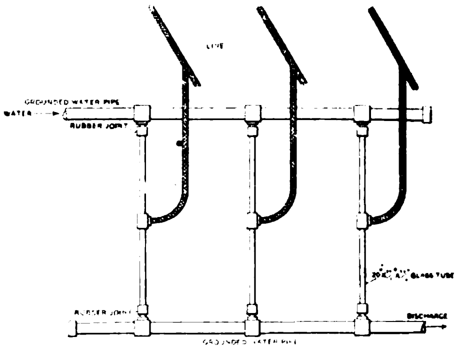

FIG. 2.

Water Resistance Static Discharger.

At the Paderno station of the Milan Edison Company a different arrangement of water resistance static discharger was being installed at the time of the writer's visit. It consisted of only three glass water tubes, but of greater diameter and length than those used in the Morbegno station. In this case it was also expected that the device would give satisfactory results.

Summarizing the observations made by the writer, the best practice of to-day for the protection of Italian transmission lines indicates that the plan illustrated in Fig. 3 should be adopted. The plan shows that:

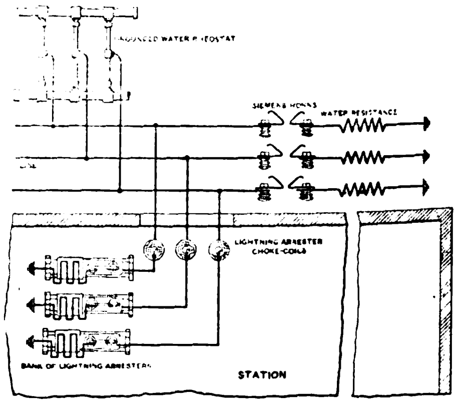

FIG. 3.—SCHEME OF STATION PROTECTION.

1. The terminals of the transmission lines should be extended in a direct line some distance away from their entrance

---

[*] Paper presented at the 200th meeting of the American Institute of Electrical Engineers, New York, October 27, 1905.

into the station, and the ends should be equipped with Siemens' horn arresters grounded through water resistances.

2. On the line side of the branch entering the station a water resistance static discharger should be installed.

3. Choke coils and ordinary lightning arresters should be installed inside the station. Possibly choke coils of the series lightning arrester type should also be added.

4. Siemens horn arresters should be used on the poles along the line only after careful study of the installation. Series lightning arresters, with Siemens horn arresters, or ordinary lightning arresters may, however, be installed at particular points; as, for instance, where a line divides into branches, or at special points of a line installed in a mountainous country.

BELT COAL CONVEYORS.*

BY FRANCIS H. DAVIES.

In the design of power stations not favored with facilities that render such apparatus unnecessary, the question of coal conveying gear is always one of some moment; but when considered in connection with the mammoth power undertakings that are now springing up in all parts, this section of the auxiliary gear assumes an importance that gives it a position among the leading features.

The available ways and means of carrying coal from place to place are indeed legion, and in many instances, the ingenuity that has been brought to bear on the details of such apparatus is remarkable and interesting to follow; in this article, however, it is proposed to deal only with that class of machine known as the belt conveyor, for the reason that in Great Britain, at any rate, it is less understood and therefore, perhaps, less trusted than the familar "bucket," "worm," and "push-plate" types.

Unlike the above, it is difficult to fix any date for the inception of the belt conveyor; it would appear that as long as belting has been known and used, it has been adapted to a more or less crude manner to this purpose; consequently, dates of patent applications, the usual source serve only to mark epochs in the history of the subject, and cannot necessarily give any idea of when it entered the realm of things that be. Belt conveying has unquestionably been evolved, and in view of its recent adoption on a large scale in sundry power houses, both in Great Britain and America, and the improvements that are now enhancing its value to the engineering world, it may not be out of place to consider one or two of the old designs which were so notoriously bad as to have left their mark on the credit of the system, even to the present day. Broadly speaking, the disadvantage under which belt conveying suffers is high cost of upkeep due to the wear and tear of the belt itself, not to that of its pulleys or gearing in any way. On the other hand, broadly, its advantages are low first cost, greater reliability, having fewer parts to break down than any other apparatus, and the extremely small amount of power that it absorbs in operation. These two last features, particularly the latter, are of such obvious importance, and so pronounced, that they are generally accepted as a set off against the disadvantage of costly upkeep; and there are not wanting enthusiasts who go so far as to say that with well-designed and carefully tended plant the high repair bogey is nowadays an utter myth. Many, no doubt, may hold opposite opinions, but it is significant at least that two of the largest electrical power stations in the world, viz., that of the Underground Electric Railways of London at Chelsea, and the immense installation of the Interborough Rapid Transit Company of New York, have quite recently been fitted with belt coal conveying gear on a large scale, and it is unlikely in either case that such a course would have been taken except upon the very soundest of grounds.

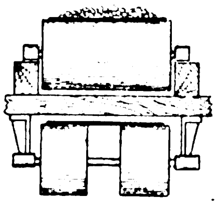

FIG. 1.

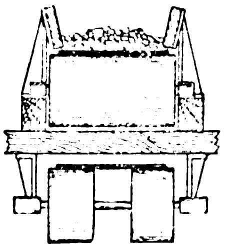

FIG. 2.

As is only natural, the earliest form of belt conveyor differed in no degree from an ordinary driving belt. It consisted of an endless belt of cotton duck generally faced with a thin sheet of india-rubber, running over flat pulleys as shown in Fig. 1, the return, or underneath side of the belt, being supported at intervals by suitable idle pulleys. Needless to say, this primitive arrangement was soon found to be unsatisfactory; it was only capable of carrying a disproportionately small amount of material, owing to the tendency of the latter to fall off the belt; it had to be kept very tight to prevent jarring at the pulleys and consequent shaking off of the load; and chiefly owing to this latter reason, the loss of power in the bearings was considerable. Further, it was only capable of slow speeds, and the amount of material delivered to the belt had to be most carefully and evenly regulated at all times. This system was found most suitable for conveying light stuff such as grain, as the resistance to motion created by the air tends to keep the load in a central position, with the result that with care speeds of 300 to 400 feet per minute may be attained. On the other hand, heavy material such as coal is not in any way affected by the air resistance, and consequently tends to spread itself out, necessitating much lower speeds and more care in working.

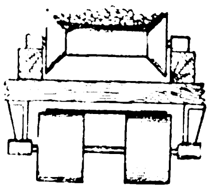

FIG. 3.

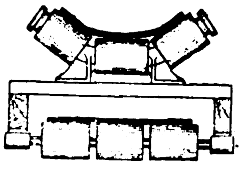

FIG. 4.

Perhaps the most obvious remedy for these faults lies in the arrangement shown in Fig. 2, in which it will be noted that planks of wood have been fixed on brackets at each side of the belt, with the object of keeping the material from falling over the edges. As far as this is concerned the skirting board system is satisfactory, but it introduces a very considerable fault that militates against the improvement which it effects.

It is found that the spaces between the underneath edges of the planks and the belt become full of the material that is being conveyed, and as to a certain extent this latter is wedged in and jammed, the result is bad cutting of the belt at the edges, which soon reduces it considerably in width.

This brings us to the stage of development which is the precursor of all modern systems, although, per se, still full of faults. The double conical pulleys over which the belt runs (Fig. 3) force the sides of the latter up, forming a continuous trough; but as there is a wide difference between the peripheral speeds of the inner and outer edges of the cones a large amount of slip occurs between them and the belt, which slip deteriorates the under surface almost as badly as the former system. The only feasible method of troughing a belt—and such is found to be absolutely necessary for conveying purposes—is to employ separate and distinct idle pulleys at the sides, as shown in Fig. 4, which is an end view of the well-known Robins system of belt conveying. By this arrangement there is no slip, and the wear and tear of all parts is reduced to a minimum. Occasionally the belt evinces a tendency to lift, in which case the spindles of the two side idlers are fitted with small rollers, placed at right angles, so as to bear on the edges of the belt and keep it in position (Fig. 5). A further refinement shown in this figure, and used at the place where the load is fed on, is that of skirting boards placed well clear of the edges of the belt, but so arranged as to protect them from the falling coal, which is thus caused to impinge on the heap in the center of the belt.

---

*From the "Electrical Review," London.

This is the type of conveyor installed at the power house of the Interborough Rapid Transit Company of New York for elevating and carrying coal to the bunkers. In this particular case all the conveyors are from 300 to 500 tons per hour capacity and use a belt 30 inches wide. A very similar arrangement made by Mead, Morrison & Co., New York, is used at the Lot's Road power station of the Underground Electric Railways Company of London. The belt conveying coal to the crushers is 30 inches wide with a length of travel of 190 feet, and although its full working capacity is 240 tons per hour, a 10 hp. motor is ample to operate it. Two other similar conveyors are installed at Lot's Road for carrying the coal after crushing, etc., to the bunkers. Like the former they are horizontal, but only 24 inches wide, and as their length of travel is nearly 500 feet, they require more power, each being driven by a 20 hp. motor.

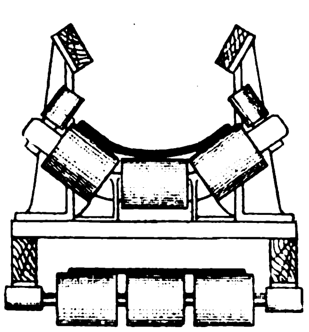

FIG. 5.

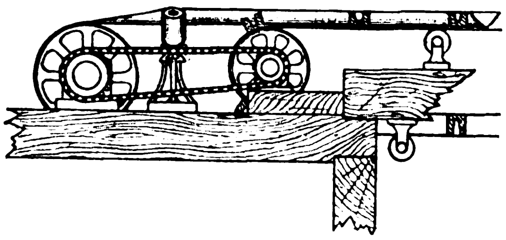

FIG. 6.

A recently introduced and ingenious method of belt conveying, is that known as the Ridgeway two-belt system illustrated in Figs. 6 and 7. Referring to these, it will be seen that running on separate and smaller pulleys there is an internal flat belt, fitted equidistantly with white wood blocks of an internally curved shape, which are riveted to it.

The driving pulley of this carrying belt is rotated through the agency of a compensating gear from the main power shaft of the conveyor, and the belt is provided on the top side with its own idle pulleys where necessary. The upper or conveying belt runs on flat pulleys at the driving and the driven ends, but at the points where it enters and leaves the blocks of the carrying belt, centering rolls are provided as shown, the duty of which is in the first case to give the upper belt the required curve before entering the blocks, and in the latter, to prevent its springing out of them as it approaches the end of its travel, and tends to go flat. On the return path, both carrying and conveying belts run on the same idle pulleys as shown, the blocks of the former bearing on the inside of the latter. The two belts run at exactly equal speed, although quite separate, and it is claimed that there is no rub between them, and that, with the exception of the power required to rotate the bottom idlers, the carrying belt does all the work, thus minimizing the wear and tear of the conveyor.

Reverting to the Robins type of conveyor, which may be taken as representative of usual practice, the width of the belt and the weight of the load determine the distance apart of the idler pulleys; but generally, those whose function it is to trough the belt are placed from 3 to 6 feet apart, while the lower or return set may be anything from 8 to 12 feet. Where circumstances are favorable, it has sometimes been possible to run the belt to a very great degree on simple flat pulleys, placing one of the centering type; say, at every fourth position to shift the material, which naturally spreads out when the belt is on the flat-back, to the center. The excuse for adopting such a method is, of course, cheapness; but it is doubtful if it is advisable excepting for the very lightest class of load conveyed at high speeds.

Of all the auxiliary gear attached to belt coal conveyors, perhaps that which provides for the loading of the belt is the most important. The chief cause of wear lies in the impact of the coal, and it follows, therefore, that this must be reduced to the lowest possible amount by feeding through a properly-shaped inclined shoot in the same direction as the travel of the belt, and as near as possible at the same speed. Vertical feeding is very harmful, and should never be resorted to.

Another important auxiliary detail is the tripper, which may be fixed or movable, automatic or otherwise, as occasion requires, and is used for unloading the belt at other places than at the end of its travel. It is shown diagrammatically in Fig. 8, and as will be seen, consists essentially of two pulleys, placed almost vertically, through which the belt takes an S-shaped path, the load leaving it at its first bend, and falling into a shoot arranged to deliver at the side. This tripper may be fixed in one position, or it may be movable, either by hand or through gearing by the belt itself, in order to distribute the coal uniformly in the bunkers. Also, by the agency of two parallel shoots it may be made automatic, the coal, after filling one bunker, and therefore the shoot, passing down the second one back to the portion of the belt that has been through the pulleys.

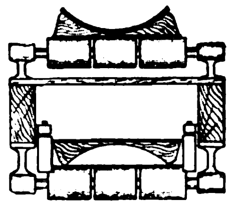

FIG. 7.

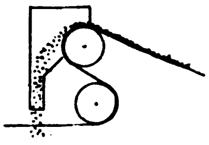

FIG. 8.

The use of belt conveyors on an incline, such as that shown in the diagram, is quite practicable under suitable conditions. A continuous supply of load is necessary if an incline approaches an angle of 30 degs., but with smaller angles a material such as coal will not slip appreciably even when fed intermittently. As previously stated, the wear of the belt has been the chief deterrent to the widespread use of these conveyors. It did not require much experience with them to show that while a rubber facing of the right kind withstood the wear very well, the canvas duck which forms the principal part of the belt deteriorates very rapidly where exposed to the cutting action of the load. For this reason conveyor belts are now made with a specially prepared rubber face of considerable thickness in the center, where most of the wear takes place. To allow it to assume a troughed shape easily, it is usual to decrease the thickness of the canvas backing in the middle, compensating for this by additional rubber. The thickness of the latter must depend upon the nature of the material the belt is destined to carry. Grain and such light stuff only require a thin layer, but coal being comparatively heavy and having many cutting edges calls for a thickness in the center of approximately a quarter of an inch of rubber, which may be thinned down to an eighth or a sixteenth of an inch at the edges where the wear is less.

As regards speeds and widths, the former may vary very largely according to conditions and individual ideas on the subject, and may be anything from 100 to 900 feet per minute, although this second figure is by no means usual or to be recommended, as it puts very hard work on both the pulleys and belt; 400 feet per minute is fair speed for level work, and for elevating this may be increased with advantage.

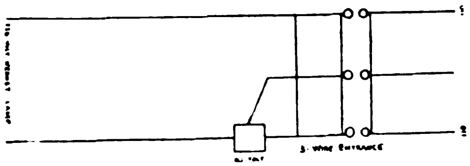
Widths range generally from 12 up to 36 inches, and a troughed belt of the latter size will carry nine times as much as one of the former, the capacity varying as the square of the width.

WRINKLES.[*]

EDITED BY H. C. ABELL.

Using a 110-Volt Meter on a 220-Volt Circuit.

The following is a rough sketch of a scheme that works all right when you want to meter a load on a 220-volt circuit, and have nothing but a 110-volt meter in stock. Run the line through the field of the meter in the usual manner, and the other side of the line goes to the lamp. Then for the shunt tap bring a wire from the center line, or the 110-volt side, and you are all right by using a constant of (2).



110-VOLT METER AND CONNECTIONS.

H. E. RYDER, Marlboro, Mass.

Trimming Municipal Arc Lamps.

We find a trimmer's cart drawn by a horse very economical, inasmuch as it requires only one man to trim our lamps, at the same time replacing all outer globes that may be broken and cleaning all inner globes. The cart is so arranged that it will hold 100 inner globes and 3 outer globes. Our lamps are General Electric, Form 3, 6.6-ampere, series-alternating, furnished by 50-light tub transformers. From April 1 to November 1 the lamps require new trimming every seven days, and from November 1 to April 1, the nights being longer, they require trimming every six days. Hence the trimmer has to make a complete round on all circuits in seven days during the summer-time, trimming about 90 lamps per day, and during the winter trimming about 95 lamps. The trimmer, having made his cart ready the evening before, makes his start at 7 o'clock in the morning, completing his day's trimming in five to seven hours, then returning to the electric station and washing all the inner globes removed from the lamps, and putting them on the dripping rack to dry; then he takes the globes that were washed the previous day and puts on bottom carbon holders and inserts bottom carbons. He then proceeds to arrange his cart ready for the next day's trimming.

R. A. HAMMACK,
Montgomery, Ala.

Electrical Assistants Wanted.

The United States Civil Service Commission announces an examination on November 22 at the Brooklyn Post Office to secure eligibles from which to make certification to fill about six vacancies in the position of electric assistant in the Signal Service at large, for a period not exceeding six months, at the rate of $75 per month during such employment, and vacancies as they may occur in any branch of the service requiring similar qualifications. Applicants should at once apply either to the United States Civil Service Commission at Washington, D.C., or to the secretary of the board of examiners at the New York Custom House for application, Form 1,312. No application will be accepted unless properly executed and filed with the Commission at Washington.

Electric Heating.

President Blood, of the National Electric Light Association, has appointed Mr. James I. Ayer to report on the progress of electric heating at the next convention of the association.

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until November 14 for furnishing Eastern Navy Yards with the following electrical material: Schedule 205, insulated iron wire, generating sets; schedule 206, electric cable and sockets; schedule 207, electric cable and insulators, copper wire. Blank proposals and specifications can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCT. 24, 1905.

Electric Railways and Appliances.

802,485. Railway Signal System. Charles W. Stiff and Claude L. McKesson, Colorado Springs, Col. Filed Dec. 1, 1904.

802,498. Retaining-Clip for Third-Rail Insulators. William Courtenay, New York City. Filed Dec. 6, 1904.

802,539. Trolley for Electric Cars. George F. Warburton, Denver, Col. Filed Aug. 6, 1904,

802,853-854. Electric Railway-Signal. Elwood W. McGuire, Richmond, Ind. Filed March 6 and 30. 1905.

802,749. Electric Signal for Railways. Frederick H. Gray, Leavenworth, Kan. Filed March 7, 1905.

Electric Lights and Appliances.

802,370. Illuminating Apparatus. Paul E. Collins, Boston, Mass., assignor, by direct and mesne assignments, to the Electric Novelty Machine Company, same place. Filed Aug. 29, 1904.

802,652. Dash Electric Headlight. Thomas Millen, New York City. Filed May 15, 1905.

Electrical Machinery and Apparatus.

802,369. Circuit-Controller or Electric Switch. John P. Coleman, Edgewood, Pa., assignor to the Union Switch & Signal Company, Swissvale, Pa. Filed April 1, 1904.

802,237. Insulator for Electric Wires. Clarance A. Humphrey, Elyria, O. Filed Feb. 15, 1904.

802,451-452. Electric Motor and Induction-Motor Device. Dugald C. Jackson, Chicago, Ill., assignor of one-half to Murray C. Beebe, Pittsburg, Pa. Filed March 8, 1900. Renewed Jan 26, 1905.

802,736. Electric Fuse. Frank B. Cook, Chicago, Ill. Filed July 9, 1904.

802,767. Current-Motor. Frederick B. Marvin, Paterson, N. J. Filed Dec. 1, 1904.

802,945 to 802,959. Electro-Magnetic Valve and Electro-Magnetic Valve Controlling System. Isaac G. Waterman, Santa Barbara, Cal. Original application filed June 25, 1903. Last application filed Feb. 8, 1904.

Telephones and Telephone Apparatus.

802,387, Telephone Cut-Out and Switch. Owen M. Galloway, Edward B. White and Adam D. Neptune, Mountayr, Ia. Filed Sept. 1, 1904.

802,513. Attachment for Telephone-Transmitters. Louis St. J. Johnson, Baltimore, Md. Filed June 18. 1902.

802,569. Telephone-Directory Holder. Louis St. J. Johnson, Baltimore. Md. Filed May 21. 1903.

802,644. Telephone Desk Set. William Kaisling, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Nov. 23, 1903.

802,654. Telephone-Directory. Paul C. Murphy, Seattle, Wash. Filed Nov. 8, 1904.

802,671. Telephone-Exchange System. Harry G. Webster, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Feb. 14, 1903.

Miscellaneous.

802,413. Electrical Apparatus. James E. Seeley, Los Angeles. Cal., assignor to the Synchronous Static Company, same place. Filed July 20, 1904.

802,417 to 802,432. Space Telegraphy. John S. Stone, Cambridge, Mass., assignor to Willam W. Swan, trustee, Boston, Mass. Original application filed Feb. 23. 1904. Renewed Aug. 17, 1905.

802,477. Thermostat. Frederick W. Robertshaw, Pittsburg, Pa. Filed Feb. 10, 1904.

802,480. Electric Interrupter or Vibrator. James E Seeley, Los Angeles. Cal., assignor to the Synchronous Static Company, same place. Filed Feb. 1, 1905.

802,573. Alarm System. John M. Latimer, Philadelphia, Pa, assignor, by mesne assignments, to the Consolidated Fire Alarm Company. Filed Sept. 11, 1902.

802,577. Conduit for Electric Wires. Robert W. Lyle, New York City. Filed Feb. 10, 1903.

802,619. System of Electrical Distribution. John H. Anderton, Boston, Mass., assignor to the Albert and J. M. Anderson Manufacturing Company, Portland, Me. Filed Feb. 28, 1905.

802,675. Electric Bell. Charles E. Avery, Jersey City, N. J., assignor to the Manhattan Electrical Supply Company. Filed March 16, 1904.

802,684. Heat-Coil. Frank B. Cook, Chicago, Ill. Filed April 8, 1905.

802,697. Circuit-Controlling Device. Harry T. Johnson, Jersey City, N. J. Filed April 2, 1904.

802,753. Electric Bell-Ringer. Ira W. Hall, Brownwood, Tex. Filed March 21, 1904.

802,896. Electric Lock. Nicholas W. Webb, New York City. Filed Nov. 1, 1904.

[*] Paper presented before the National Electric Light Association at its 28th convention, held at Denver-Colorado Springs, Col., June 6-11 1905.

THE TELEPHONE WORLD.

Deal Closed for Telephone Properties.

A company headed by A. H. Bauer, of Bauer Brothers, St. Louis; H. C. Stifel, treasurer of the Althomer & Ralings Investment Company, St. Louis, and James S. Brailey, Jr., of Toledo, O., lately closed a deal for the controlling interest in the Indianapolis Telephone Company and the New Long Distance Telephone Company of Indiana. The consideration was not made public, but is said to involve about $710,000.

Speaking for the new company Mr. Brailey said. "We have closed a deal whereby we have become interested in both the Indianapolis and the New Long Distance Telephone Companies, and we have, at the same time, an understanding with certain local interests by which the management of the companies will be satisfactory to us."

Mr. Brailey and his associates declared emphatically that the Bell Telephone Company is in no way whatever cocnected with the deal. Mr. Brailey said they bought it with the understanding that the companies shall remain Independent, and that they shall be held largely by local men. He added that the management of the two companies will not be molested at this time. Mr. Brailey and his associates control the Toledo Home Telephone Company of Toledo; Mr. Stifel is largely interested in the Kinloch Independent Telephon Company of St, Louis and Mr. Bauer is a heavy stockholder in the Kansas City Home Telephone Company.

It is understood that they paid 55 cents on the dollar for stock in the New Long Distance Company. A few days ago, it is said, they deposited $75,000 with the Union Trust Company as a guarantee of good faith. The Trust Company bought up a lot of the stock for the new owners. It is understood that the largest block of stock in the New Long Distance Company was held by the estate of the late S. P. Sheerin, who was a moving spirit in both organizations. Louis Holloweg, of Indianapolis, is said to have controlled the Indianapolis company.

Among the Toledo people interested with Mr. Brailey in the deal are Ashbrooke & Co., Secor & Bell and Clarence Brown.

The New York Board of Estimate and Apportionment, at its meeting on Friday, called up the application of the Atlantic Telephone Company, which proposes to erect and establish a system with a view to giving a telephonic service in New York for 5 cents a call. The application was held over for a fortnight for further reports concerning the rights of other concerns.

The Denmark, Me., Telephone Company, capitalized at $10,000, has the following officers: President, E. L. Head; treasurer, C. L. Wentworth; clerk, M. H. Wentworth, all of Denmark.

The Knox County Home Telephone Company of Vincennes, Ind., will issue $125,000 preferred stock. I. E. Gardner, secretary.

The Nebraska Telephone Company is preparing to rebuild its lines in Central City. Between $10.000 and $15,000 will be expended.

The Wisconsin Telephone Company may retire from Kenosha within a short time, and leave the field to an Independent company. Negotiations are now pending between the officials of the Wisconsin company and those of the Citizens' Company of Kenosha for a consolidation of the two plants. The price of the combined plants is said to be $200,000, and it is thought that the new company will be formed shortly. The deal will eliminate telephone competition in Kenosha and will give the holding company a business of more than 1,800 subscribers. It is understood that the company will continue the long distance service by use of the Wisconsin company's wires.

G. R. Fuller, general manager of the Rochester, N. Y., Telephone Company, is devoting a portion of his time to Syracuse, looking after the installation of the new telephone system there. "As soon as the Syracuse system is ready to be operated," said Mr. Fuller, "Utica, Syracuse and Rochester will be connected by toll lines of sufficient capacity to care for all the business we can handle. We have fine service between Utica and Albany. The Independent Telephone Securities Company does not control any line east of Little Falls, but it has satisfactory arrangements with other companies whose lines extend to Albany."

Systematic thefts for several years of copper wire and other supplies, amounting to thousands of dollars, from the Newark, N. J., branch of the New York & New Jersey Telephone Company were disclosed last Thursday by the arrest of a junk dealer, in whose possession several hundred dollars' worth of the stolen goods were found.

The Converse, Ind., Telephone Company, which for the past five years has been a sublicensee of the Central Union Telephone Company, has severed its connection with the Bell interests and now connects only with the Independent system.

Work on the telephone conduit system, for which the East Tennessee Telephone Company was granted a franchise in Chattanooga several months ago, will begin at on early day. Captain A. G. Sharp is superintendent of the company,

The Independent interests propose to enter Greene County, Pa., starting at Waynesburg, in competition with the South Penn Telephone Company, which has lately allied itself with the Bell interests as a sub licensee. It is said that company will pay $2 a year rental for each Bell instrument.

The Northern Pacific Railway Company is constructing a long distance telephone line from Fargo, N. D., to St. Paul by way of Brainerd, Minn.

The New England Telephone Company has started the foundations for a new $20,000 office and exchange building at Burlington, Vt.

The Granville, N. Y., Telephone Company has increased its capital stock from $50,000 to $250,000.

The Northwestern Telephone Company has applied for a franchise in North Branch, Minn.

The fourth telephone company desiring a general franchise from Milwaukee, Wis., to establish an Independent exchange, made its appearance lately at the meeting of the common council, and it is expected that a fifth concern, which is at present being organized in St. Louis, will present its ordinance at the next session. The latest aspirant for a franchise has been incorporated under the name of Cream City Telephone & Telegraph Company, and as far as favorable conditions to the city are concerned, it is believed to have outbid all the former applicants. Back of the enterprise, it is said, is a syndicate of American capitalists, headed by W. D. Shroud, of St. Louis, which has just completed a new exchange in the city of Havana, Cuba, in which enterprise it had invested not less than $1,500,000. The local attorneys representing it in Milwaukee, are Wliam Kershaw and Walter Schinz.

The Marathon-Killawog, N. Y., Telephone Company has placed an order with the Century Telephone Construction Company of Buffalo for a switchboard for its exchange in Marathon, and expects to install 300 telephones in southern Cortland and northern Broome Counties. This company will have direct connection with the Inter-Ocean Telephone Company at Cortland.

The Palermo, Me., Telephone Company has been formed to construct and operate telephone lines from Palermo to China, Albion, Somerville, Hibert's, Gore and Liberty. The officers are: President, Silas E. Bowler; treasurer, W. W. Turner, both of Palermo.

The Buffalo, N. Y., aldermanic street committee has resolved to report in favor of the petition of the Frontier Telephone Company to erect and maintain at specified points street 'phones to be affixed to existing lamp posts with underground lateral connections.

Work on installing the Independent telephone system, known as the Home Automatic Telephone Company, for which Herman & Schatzman, of St. Louis, are handling the securities, was lately begun in Quincy, Ill. The plant will cost $500,000. R. S. Spencer, Charles Sutter and J. H. Murphy, all of St. Louis, are among the principal bondholders.

A recently organized concern, known as the Erie Wyoming Telephone Company of Sardinia, N. Y., is capitalized at $10,000. The directors are R. R. Allen, A. W. Phelps and H. B. Freeman.

Representatives of the Long Distance Telephone & Telegraph Company have been in the section of Lynnville, Tenn., securing rights of way and making general investigations in regard to locating an exchange in that part of the county.

The New York & New Jersey Telephone Company has increased its capital stock from $15,000,000 to $50,000,000. The amount of stock so far issued is $13,770,100.

The Cornwall Telephone Company of Cornwall, N. Y., capitalized at $5,000, has been organized with the following directers: W. B. Goodwin, Learned Hand and G. Morrell.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Alger, O.—This village will vote November 7 on issuing bonds to the amount of $3,500 for the purpose of securing electric lights.

Argenta, Ark.—This city will install an electric light plant and waterworks at an estimated cost of $65,000, and desires to engage a first-class mechanical engineer. C. J. Humphreys is secretary and collector of the board and W. C. Faucette, mayor.

Arlington. O.—The saw mill and electric light plant of Adam Beach in this place, which were recently destroyed by fire, will be rebuilt at once.

Auburn, Neb.—The city council has entered into a contract with the Auburn Mutual Lighting & Power Company to light the streets, lanes and alleys of the city with electricity for a period of five years.

Bay Spring, Miss.—The Bay Spring Lumber Company has been reorganized with a capital stock of $100,000, and will enlarge its plant and build an electric light plant to furnish the town with lights. The incorporators are W. B. Rogers, L. L. Denson, John Miller and others.

Birdsboro, Pa.—Plans are being made for an electric light plant here. It will be erected for the purpose of furnishing the residents of the village with better lighting facilities.

Bishopville, S. C.—The Bishopville Light & Power Company has been incorporated with a capital stock of $17,500 by A. C. Baskins, George M. Stuckey and R. W. McLendon.

Burlington, Vt.—The board of aldermen has passed a resolution appropriating $5,000 for the extension of the municipal electric light system.

Dana, Ind.—Work has been begun on the new electric light plant. The town is putting in the plant, and is buying nothing but the best of equipment.

Decorah, Ia.—W. H. Burtis has been granted an electric light franchise.

Far Rockaway, N. Y.—The Queens Borough Gas & Electric Company of this place will install a Curtis steam turbine and a generator, which will double the capacity of the generating power. The company found it necessary to make this improvement because of the extension of its gas mains and electric lines to the town of Hempstead.

Geary, Okla.—The Geary Electric Light & Power Company has been incorporated with a capital stock of $5,000 by J. J. Paige, Edward Ruggles, J. S. Moffitt and others.

Geneva, Ind.—W. R. Thurston, of Bern, accompanied by Messrs. Olds and Hartmann, of Ft. Wayne, were lately here looking after the electric lighting franchise which was granted about two months ago. Messrs. Olds and Hartmann take $5,000 of the stock, leaving a like amount to be subscribed for by the local capitalists.

Gravette, Ark.—G. W. Dunbar, of this place, who claims to be backed by Kansas city men, has made a proposition to the city council for an electric light plant and waterworks system.

L'Anse, Mich.—The $10,000 bonds issued by the village for the erection of a municipal electric lighting plant have been purchased by the Houghton National Bank. The council expects to have the plant in operation by December 1.

Lehigh, I. T.—The city council has granted a franchise for electric lights and power to the Consumers' Ice Company.

Lenoir, N. C.—The town commission has granted a franchise to E. C. Ivey for an electric light plant.

Malvern, Pa.—The Malvern Electric Light Company has been chartered with $5,000 capital stock.

Meredith, N. H.—The plant of the Meredith Electric Light Company has been purchased by the Laconia Electric Light Company, and the power station here will be discontinued. It is the intention of the new management to extend the wires from Lakeport to this place, a distance of about six miles, and the current for operating the Meredith light plant will be taken from the main power station. The work of setting poles and stringing wires will begin at once.

Morristown, Minn.—The citizens are agitating the establishment of an electric light plant.

Newport, Ky.—Harvey Myers, James H. Young and B. Bramiage have incorporated the Municipal Light, Power & Fuel Company with a capital stock of $200,000 to operate an electric light and power plant.

Ridgefield, Conn.—The Ridgefield Electric Light Company has purchased a site near the Ivy Hill crossing upon which the company will soon begin the erection of a power house and other buildings.

Rockvale, Col.—This town has granted a 25-year franchise to the Arkansas Valley Electric Light Company to put up poles and operate lights within the corporate limits of the town.

Roslyn, N. Y.—William K. Vanderbilt, Jr., heads a petition filed with the town board of North Hempstead asking that body to establish a lighting district at Lakeville and light the streets, avenues, public highways and places by electricity.

Roseville, Ill.—The Roseville electric light plant was lately sold to G. W. Rayburn.

Shawnee, Okla.—The Shawnee Union Electric Company will erect an electric light and power plant. The company is capitalized at $250,000.

Sheboygan, Wis.—Congressman Charles H. Weiss, of Sheboygan Falls, has purchased the entire $12,000 issue of bonds voted by the city of Princeton to acquire the local electric lighting plant. The bonds were bought for $11,900 and bear 4 per cent. interest.

Sparta, Ga.—The citizens have voted affirmatively on the bond issue for the construction of an electric light plant. R. W. Wood, mayor.

Westfield, N. Y.—The United States Canning Company is preparing to install its own electric light plant.

STREET RAILWAYS.

Ambler, Pa.—Work on the new trolley line from Center Square to this place will begin at once.

Ames, Ia.—This city will have an electric street car line next spring.

Baraboo, Wis.—The project of building an electric road from Kilbourn to Devil's Lake by way of this city has been revived. The Dells Company of Kilbourn is willing to supply most of the money for the proposed road.

Brazil, Ind.—David Morgan, secretary of the Indianapolis & Ohio Valley Traction Company, says that the company has accepted the franchise granted by the city.

Hughesville, Pa.—A new trolley line is to be built by Bloomington people from this city to Muncy. John G. Harman and E. F. Carpenter are at the head of the scheme.

London, Ont.—The talk of an electric line railway from Sarnia to this city has been renewed.

Schenectady, N. Y.—The Schenectady & Stamford Electric Line Company has been incorporated with C. T. Kromer as president.

Seymour, Ind —A meeting was lately held in this city by a company at the head of which is E. S. Russell, of Chicago, which proposes to build an interurban electric line from Columbus to French Lick.

Steubenville, O.—It is stated that the Wheeling Traction Company will shortly commence the work of building its new line from this city to Mingo.

Trenton, Ill.—Will O. Garvin, of the Farmers' Exchange Bank, is in correspondence with the Chicago capitalists who want to take up the matter of building an electric railway line between here and Chillicothe.

Wellsburg, W. Va.—A charter has been issued to the Wellsburg & Washington Electric Railway Company for the purpose of building an electric line from this city to Washington, Pa.

POWER PLANTS.

Atlanta, Ga.—A new electric light and power company will begin to do business in this city and various cities of Georgia during the early part of next year. All the plans have been completed. It is also declared that the investment capital that is involved amounts to more than $3,000,000 and that a number of prominent capitalists are interested in the proposition.

Birmingham, Ala.—The Coosa River Power Company, at the head of which, it is reported, will be Regert Zell, of this city, will soon be organized here. The amount of capital stock is not known. The object of the company will be the development of water power at Lock 3 on the Coosa River, and its transmission to Anniston by electricity.

Cadillac, Mich.—A petition from the Manistee River Power Company to be allowed to dam the river for power will be discussed by a special meeting of the Wexford supervisors on November 15. The plant will be modern in every detail and develop 3,000 hp. William Douglas, a Manistee millionaire lumberman, is president.

Rockville, Conn.—A power plant is to be erected for the Springville Manufacturing Company to cost $12,000.

Winnipeg, Man.—The Great Falls Power Company is to proceed at once with the development of 50,000 electrical horse power for transmission to this city. The flotation of the bonds of the company has been undertaken by H. M. Byllesley, of Chicago, who is backed by a group of 10 well known American capitalists. The bond issue is $6,000,000, all of which has been guaranteed.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅜@16⅝c.; Lake 16⅜@16⅝c.; casting, 16⅛@16⅜c.

Reports that the Chicago Telephone Company will increase its dividend rate are denied by the officers.

The National Carbon Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable November 15 to holders of record November 4.

The Texarkana (Ark.) Electric Street Railway, owned and operated by the Texarkana Light & Traction Company, has gone into the hands of Col. E. J. Spencer, of St. Louis, as receiver.

New York Metropolitan Street Railway shares have declined nearly 10 points within the past week without important rallies. It is said that the traders known as the Tammany crowd are heavily long of Metropolitan.

Shareholders of the San Francisco, Oakland and San Jose Electric Railway Company will meet on December 21 to vote on creating an issue of $1,500,000 second mortgage bonds, to provide for extensions and new rolling stock.

The preferred stock of the Western Telephone Company (Bell) has recently sold down to 91, against a high price of 104 last February. The common has declined from 22½ to 14. There is $16,000,000 of each issue outstanding.

The income bondholders' committee of the United Railways Company of Baltimore met on Friday last but failed to arrive at any definite conclusion looking to the refinancing of the road. The committee has now $5,000,000 of the income bonds in its control, out of a total issue of $14,000,000.

The right of stockholders to subscribe to the new stock of the New York and New Jersey Telephone Company will expire on November 30. Payments to be made as follows: 25 per cent. December 1, 1905; 25 per cent. April 1, 1906; 25 per cent. July 1, 1906, and 25 per cent. October 1, 1906.

Stone & Webster of Boston have bought the Nooksack power plant from the Bellingham Bay Improvement Company of Bellingham, Wash., and also the lighting franchises of the company. Plans for the plant provide for an ultimate development of a total from 12,000 to 15,000 horse power at a cost of approximately $1,000,000.

The United States Independent Telephone Company, which was recently organized to conduct a general telephone business throughout the United States, contemplates the immediate erection of a $6,000,000 telephone plant in St. Louis and the enlargement of the present apparatus manufacturing establishments in Rochester.

A representative of the Allis-Chalmers Company, when asked whether there was any truth in the report that the General Electric Company was buying stock of the former corporation and would secure representation on the board, replied: "It certainly looks like it. They will get representation on the board if they have sufficient stock to justify their admittance."

Denison, Prior & Co., of Cleveland and Boston, and Thomas Nevins & Sons, of New York, are offering for subscription $2,500,000, the unsold portion of the $5,000,000 underwriting of the Missouri Valley Electric Railway, which has been organized under the laws of Missouri for the purpose of constructing a high speed electric railway on private right of way from Kansas City, Mo., to St. Joseph, Mo.

EDITORIAL NOTES.

Factory Power From Rivers.

Rivers represent revenue to that particular class of shrewd operators who see in a broad, smooth inland stream the possibilities we are accustomed to finding only in cataracts or mountain falls. They represent revenue not only to their exploiters, but to the manufacturing interests requiring more and cheaper power to expand to their true dimensions.

The largest enterprise of its kind yet undertaken in the United States will be begun about 12 miles from Chattanooga on the Tennessee River—representing a $3,000,000 investment in real estate, machinery and civil engineering construction. The direct beneficiary will be Chattanooga, within the confines of which city now exist 400 factories, employing thousands of hands and using thousands of horse power. The Tennessee River is 1,200 feet wide at the point where a dam is to be built. The backers of the scheme are New Yorkers, but the originators are well-known city residents, who gain their special engineering information from a New York expert employed as consulting engineer.

Interference with the free navigation of the river has been avoided by means of a lock extending to within three miles of the city. This is a great advantage commercially, and was the means of gaining the consent of the Federal authorities to the construction of the dam across it. The direct improvement of Chattanooga's waterway was admitted in Congress as being the sequel to this remarkable scheme, and aided in securing government consent.

A review of the circumstances shows factories for the manufacture of wooden, iron and cotton goods, which, it is firmly believed, will be doubled in number by the introduction of a new power supply. Fourteen electrical generators of 4,000 hp. apiece, a total of 56,000, will represent the amount on tap. This energy is obtained through the 35-foot drop the river takes about 21 miles beyond Chattanooga. Factory space along the river bank is now at a premium, and the demand for new sites is greater than the supply in that neigborhood. The city population has increased 10,000 with constant emigration from neigboring towns. The project now just started has caused a healthy boom, the results of which will be an industrial activity giving rise to a great increase in the number of workers, in the individual wealth and the general prosperity. The revenue derived from this power, on the basis of $50 a year per horse power—a very low estimate—will be at least $3,000,000 to the company. With the advantages due to better water facilities and the new power supply, Chattanooga may double her population before many months have passed. It will certainly double its wealth under these new and stimulating influences. Electricity is proving itself the savior of many inland towns.

* * *

The Induction Motor.

The various sections of the English Institution of Electrical Engineers are just opening their winter sessions. The section at Leeds commenced its proceedings on Wednesday, October 25, with the consideration of a paper by Mr. T. Harding Churton on "Alternate Current Induction Motors." He compared the Performance and Characteristics of motors of the induction type when provided with short-circuit, and with wound rotors, respectively; the performances of such motors on single-phase and polyphase circuits, and he also indicated, by comparisons, the extent to which the working of such motors is affected by the frequency of alternations. A particular size of machine with short-circuit and with round rotor, for single-phase and for polyphase working, and on circuits of various periodicities, was used as an example, and the results put forward in the course of the paper were obtained from actual tests on a number of machines of the same size. In each case the windings were appropriate to the circuit upon which the motor was to operate.

Curves taken from tests made upon two motors, one having a short-circuit rotor and the other a round rotor, but which were in other respects identical, showed that both the efficiency and power factor were higher with the short-circuit rotor machine. Both machines were 5 B.H.P.; speed about 1,420 revolutions, running on a single phase, 200 volt, 50 cycle circuit. The starting torque obtained with the short-circuit rotor machine was .45 full load torque with 1.25 times full load current, while the wound rotor machine gave .75 full load torque with full load current. The slip was somewhat greater with the wound rotor, but the latter would pull out of step rather sooner than the short-circuit rotor. The difference between the results obtained with the short circuit and wound rotors on polyphase working was practically the same as that on single phase, though with the polyphase system the results themselves were much better.

For the purpose of speed regulation the wound-rotor motor was the more satisfactory, though for some purposes, such as operating cranes, the short-circuit rotor with conductors of relatively high resistance, combined with graduated transformers for varying the voltage on the stator windings, was sometimes preferred to polyphase motors. A table was given showing the comparative performances with the two types of rotor with regard to starting torque and current on single and two-phase circuits of 50 cycles, 200 volts, clearly illustrating the superiority of the polyphase motor in this respect. By means of curves the efficiency and power factor were shown to be higher in the case of the polyphase motor, and the slip greater in the single-phase motor. The starting torque of the single-phase motor may be somewhat improved in several ways which involve lower efficiency on load. Here, as in most other engineering problems, "the question as to how far the running efficiency shall be sacrificed to improved starting performance is a matter of compromise." Mr. Churton held that though the single-phase could not upon equal terms compete with the polyphase motor, it was, nevertheless, in its better forms, an excellent machine.

* * *

Wireless Work of the Signal Corps.

An interesting report, particularly to electricians, has just been made by Gen. A. W. Greely, chief signal officer of the army. He regards as very praiseworthy the professional skill and exceptional ability of Capt. Leonard D. Wildman, who has charge of the wireless section of the Alaskan telegraph system, which he says, "is the only long wireless system in the world that is regularly operated as a part of a regular telegraph system, handling commercial business." This line has handled more than a million words in the year across the 107 miles stretch between Fort St. Michael and Safety. As many as 2,000 words an hour have been transmitted at times without error or repetition.

He states that the wireless work is done with an alternate current of 500 volts, generated by a 6 hp. gasoline engine. The De Forest receiver, modified by Signal Corps inventions, is used.

Gen. Greely regards the entire Alaskan system, aggregating 4,000 miles of cable land and wireless telegraph lines, as not only of the greatest military importance from a strategic standpoint, but of almost incalculable value commercially. Its use has already resulted in great benefit to the business interests of Alaska. During the year, 134,630 messages were handled, both Government and commercial. For the latter $78,000 was collected in tariffs.

Speaking of the general efficiency of the corps, Gen. Greely says: "At an hour's notice the Signal Corps can furnish field trains capable of installing and operating lines of communication to the extent of 1,000 miles. Special attention has been paid to the rapid development of lines of information as illustrated in the military manœuvres of Europe, during the South African contest and the Russian-Japanese war."

A special meeting of the stockholders of the General Electric Company has been called in Schenectady, N. Y., on December 5 for the purpose of voting upon a proposition to increase the capital stock of the company by $11,674,500, consisting of 116,745 shares of the par value of $100. This will increase the capital stock from the present amount, $48,325,500, to $60,000,000, all par value of shares $100. For the purpose of the meeting transfer books will close on November 11 and will remain closed until December 6.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A cable dispatch from Geneva, Switzerland, says that an army of Italian workmen has been brought to that city to begin the construction of the new electric line which is to take tourists nearly to the top of Mt. Blanc.

On two test votes in the Chicago City Council Mayor Dunne and immediate municipal ownership were defeated by a vote of more than two to 1. He could muster only 21 votes for his proposition, as against 27 for it two weeks ago, a loss of 6 votes. One of the votes was 45 to 21 and the other 43 to 21.

The submarine signaling system, frequently referred to in the columns of ELECTRICITY, will shortly be installed on all ships of the Cunard Line.

Deaf mutes have demonstrated that there is one kind of skilled work in which they far excel the ordinary artisan. A Chicago telephone factory, after a series of experiments, found that to the making of the delicate mechanism of the modern telephone the deaf mute, by reason of the manual development incident to constant use of the sign language, is peculiarly adapted. One hundred and fifty deaf mutes are now employed in the factory at standard wages.

It has been known for some time that experiments in electric traction were to be carried out on the Vienna railway system, at present worked by steam. According to the "Elektrotechnischer Anzeiger" a continuous current 3-wire system is to be adopted with 3,000 volts between the outers, the latter being in form of overhead trolley wires, suspended by means of side poles and span wires. At present the line between Praterstern and Hauptzollamt (about 0.85 miles in length) is being electrically equipped, the Helenengasse sub-station for converting the three-phase 5,000-volt current from the municipal electricity works to continuous current is being built, while the 800 hp. experimental locomotives are already on hand. Each locomotive has four 200 hp. motors. The controllers permit of all four motors being connected in series across the outers, or in two groups of two motors each.

THE INSTITUTE'S SILVER TABLET.

A pleasant incident at the 200th meeting of the American Institute of Electrical Engineers, held in New York City October 27, was the exhibition to the 300 members in attendance of the silver tablet presented to the Institute by the Associazone Elettrotecnica Italiana, as a testimonial in recognition of the courtesies extended to the members of the Italian society on the occasion of their American tour in August and September, 1904.

Silver Tablet Presented to the American Institute of Electrical Engineers.

The tablet is an artistic silver casting, mounted on a marble slab, the design embodying medallion portraits of Volta and Franklin, and an inscription in Latin, of which the following is a literal translation:

"By this testimonial, the Italian colleagues place on record, for all time, their reception in gracious and generous hospitalty, by their American colleagues, during the months of August and September, in the year 1904; may it be of good augury.

"Rome, the 31st day of the month of December, in the year 1904."

This tablet will be placed in a prominent position in the Institute headquarters in the Union Engineering Building, now in process of construction.

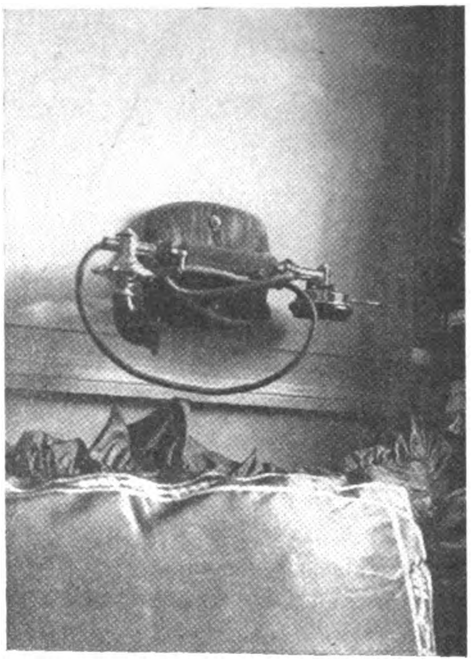
New Type of Street Car.

Montreal, Canada, has a new type of railway car. The passenger enters at the rear end and passes through a doorway, where the conductor, in a species of ticket office, collects the fare. It is stated that the company gathers in 25 per cent. more fares in this car than it did in the old type. This is one of those reforms that street railway companies find out for themselves.

ELECTRICAL FEATURES OF THE "AMERIKA."

BY IRVING THOMPSON.

Representing as it does the most advanced ideas in marine engineering, the new steamship "Amerika," of the Hamburg-American line is probably the most unique vessel afloat. In its interior arrangement it resembles a first-class hotel with its army of servants and exceptional appointments, not the least interesting and novel of which are passenger and freight elevators, gymnasium, restaurant and children's play-room. Of special interest is the extensive use of electricity, for never before were there so many devices common to shipboard which rely upon electric current for their power. The entire dynamo plant is capable of developing over 400 kw. The main plant consists of five dynamos, having an output of 750 amperes each at 100 volts. These are direct connected to high speed engines which take steam at 100 pounds pressure through reducing valves from the main boilers. These dynamos, together with the main switchboard, are located on the engine room floor, which is a considerable distance below the water line. For use in case of an emergency, such as the flooding of the engine room, an auxiliary equipment, consisting of a direct-connected unit having a capacity of 300 amperes, is placed on the Franklin deck, which is several feet above the high water line. The main switchboard is approximately 30 feet long and 7 feet high. Each dynamo has its own individual panels, upon which are mounted the necessary volt and ammeters. The board for the auxiliary installation is 4 feet 6 inches by 3 feet 6 inches. This controls the police lights in the gangways, masthead and side lights, and the illumination for the engine room and stoke holes.

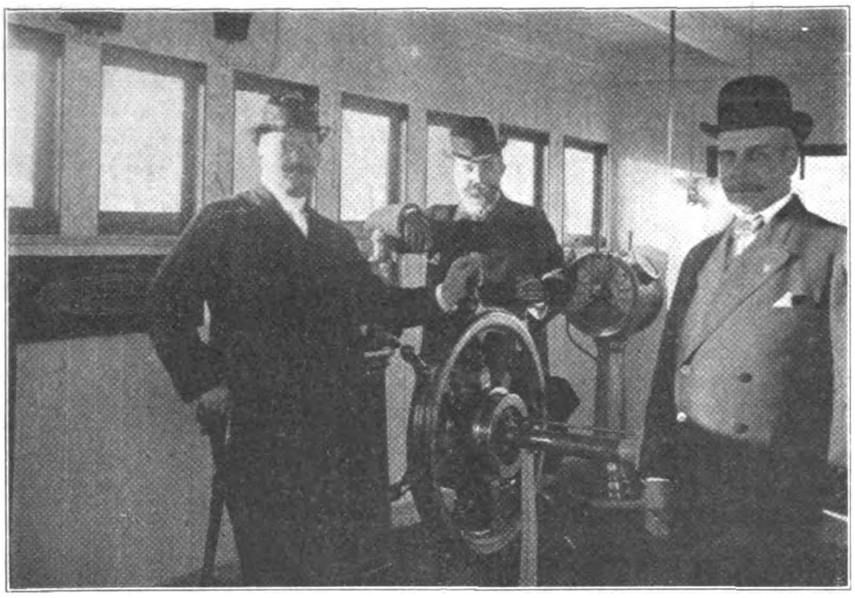


Hand Micro-Telephone in a Stateroom of the "Amerika."

For illuminating purposes there are upwards of 4,000 incandescent lights, varying in candle power from 10 to 32, including 16 and 24. There are 40 distributing boards which control the deck and cabin circuits.

One noticeable feature about the steamer is the entire absence of ventilating cowls upon the upper decks. Proper air circulation is secured through a system of forced draught, which extends throughout the vessel. For this purpose there are 19 direct motor driven Sirocco fans. These motors take from 25 to 81 amperes each. The air is drawn down through tubes from the upper deck and forced through pipes into every stateroom, cabin, saloon and passageway. In addition to the ventilating system there are two exhaust fans for removing foul air.

In the kitchen department there are two motor-driven dough mixers, six motor-driven knife cleaners, two motor-driven plate-washing machines, and motor-driven coffee-grinders and meat-choppers. In the gymnasium there are motor-driven exercising machines.



The Wheel House of the "Amerika."

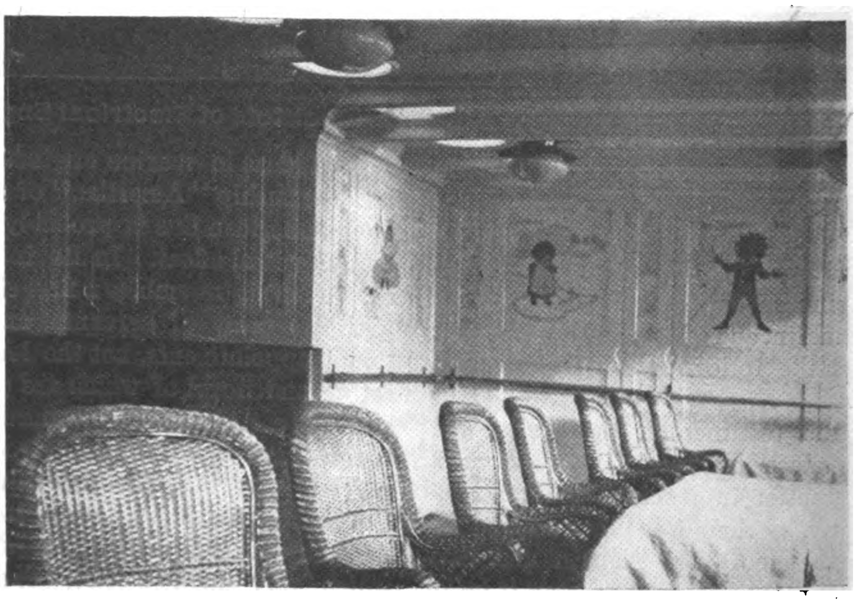
The elevators are operated by electricity as are also the two engines, revolution indicators and counters; for this purpose there are two dynamos, one connected to each propeller shaft, which operate indicators in the engineer's office and on the bridge. There is also a rudder position indicator, which shows the exact angle at which the rudder is placed.

The staterooms and cabins are heated by electric radiators which require a total of 750 amperes. Amongst other uses to which electricity is put is an electric bath, which requires 50 lights. For making cakes there are five electric griddle plates. Electric curling iron heaters are placed in all staterooms. An electric system of clocks controlled by a master clock extends throughout the vessel, as does also a fire alarm system. Electric bells are used for signaling purposes in connection with the water-tight doors. There are four separate telephone systems—one for stateroom service and one for pantry and steward's use, which employ the hand micro-telephones. One marine system which is equipped with water-tight instruments, and the Blake submarine telephone signal system. The switchboard for the stateroom system is located at the bureau of information. For the steward's use there are four annunciator boards with telephone attachment, besides the regular push-button call annunciators.

The water-tight marine instruments connect between the bridge, crow's-nest, fore and after decks, engine room and engineer's office. The submarine receiving instrument is located in the telephone house on the bridge, and connects with two receiving transmitters, located one on either side of the bow of the vessel below the water line.

In conclusion it may be of interest to note the following facts respecting this remarkable vessel. She measures in length over all 687 feet; breadth, 74 feet 6 inches, and depth, 53 feet. From the top of the bilge tanks located below the engine room floor to the apex of the engine-room skylight is a distance of 111 feet.

The engines are quadruple expansion of 8,500 hp. each. The coal consumption is approximately 260 tons every 24 hours. Her displacement is nearly 42,000 tons, which is greater than that of any other vessel afloat. In the cargo holds there is room for over 16,000 tons of merchandise. There are accommodations for 3,057 passengers, which are divided into four classes, there being an intermediate division between the second and steerage passengers.



Lighting Arrangement of Special Children's Cabin of the "Amerika."

An innovation in the nomenclature of the various decks is the departure from the usual nautical designations. Instead of main, upper, lower, orlop, etc., four of them are given the names of foremost Americans, and one is called the Kaiser. The four American-named decks are the Washington, Roosevelt, Cleveland and Franklin.

SOME EXPERIENCES WITH LIGHTNING PROTECTIVE APPARATUS.[*]

BY JULIAN C. SMITH.

This paper will deal with some experiences with lightning protective apparatus which the operating department of the Shawinigan Water & Power Company has had during the years 1903, 1904 and 1905.

The generating station at Shawinigan Falls has three generators each of 3,750 kw. capacity, 2,200-volt, 30-cycle, two-phase, and one generator of 6,600 kw. capacity, 2,200-volt, 30-cycle, two-phase. Each of these generators is direct-connected to a water-wheel operating under a head of 130 feet.

Referring now only to the long-distance lines, it is sufficient to note that the energy is delivered through a double set of bus-bars to the low-tension side of the step-up transformers. These transformers are T-connected for transforming from two-phase to three-phase. The ratio of voltage transformation is 2,200 : 50,000. The neutral point of these transformer banks is grounded, giving about

[*] Paper presented at the 200th meeting of the American Institute of Electrical Engineers, New York, October 27, 1905.

29,000 volts between each wire and earth.

In 1903, only the No. 1 Montreal line was operating. This line connected the generating station at Shawinigan Falls, P. Q., with the Montreal terminal station, situated just outside the city of Montreal. The distance from the generating station to the terminal station is 85 miles. The transmission line consists of three 7-strand aluminum cables, each of 185,000 circular mils cross-sectional area, spaced 60 inches apart, and arranged in the form of an equilateral triangle with the apex upward. These cables are supported on 35-foot poles, with cross-arms 6 feet long fastened with through bolts. The top of every pole is bored to receive a pin. All pins are 18 inches long and were boiled in stearine.

The voltage at Shawinigan is normally about 50,000; at the Montreal terminal station it is 44,000.

In the spring of 1904, a sub-station was built in Joliette, distant about 45 miles from the generating station, and from this sub-station a branch line was built to the city of Sorel. This line is about 20 miles long and is operated at 12,500 volts. The only special point of interest is a submarine cable about 5,000 feet long, by means of which the line crosses the St. Lawrence River.

In the Montreal terminal station the voltage is reduced to 2,400 and supplied to a set of 30-cycle bus-bars. From these bus-bars the frequency-changers are operated. Each frequency-changer consists of a 30-cycle synchronous motor connected to a 60-cycle generator. There are at present installed in this station five of these motor generators, each of 1,000 kw. capacity and one of 5,000 kw. capacity. In addition to these machines there are two synchronous converters, each of 1,000 kw. capacity, operating street railway circuits. It is interesting to note that the whole load of the long-distance line consists of synchronous apparatus, and that by properly regulating the fields of this apparatus the power-factor can be kept at unity.

In the fall of 1904 the No. 2 Montreal line was completed. The No. 2 line is parallel to the No. 1 line for nearly the entire distance, and in most places is not more than 100 feet distant. The second line is similar to the first except for the size of the conductor and for the fact that a ground wire is strung along the line at the neutral point of the triangle. This ground wire is connected to the earth at each pole by a wire running down the pole.

When the No. 1 line was put into service the lightning apparatus installed was as follows: At each end of the line was a bank of Westinghouse lightning arresters of the low-equivalent type and a bank of static-interrupters. The number of gaps in these arresters was decided upon after a series of tests had been made to determine the lowest practical break-down voltage. These arresters were set to discharge at about 65,000 volts. In 1904 a bank of General Electric arresters was placed on the 50,000 volt line in the Joliette sub-station. This bank was also adjusted to discharge at about 65,000 volts. In 1904 three banks of horn-arresters were put on the No. 1 Montreal line. These arresters consist of bent copper rods. The horns were spaced 6.25 inches apart at the gap, this distance corresponding to a break-down voltage of 90,000 (see Fig. 1). In 1905, when the No. 2 line was equipped with lightning arresters, three banks of low-equivalent arresters were put in, one at each end and one at Joliette. In addition to these arresters three banks of the 1905 type of horn-arresters were put in. Some changes were made in the setting of these arresters as will be noted farther on.

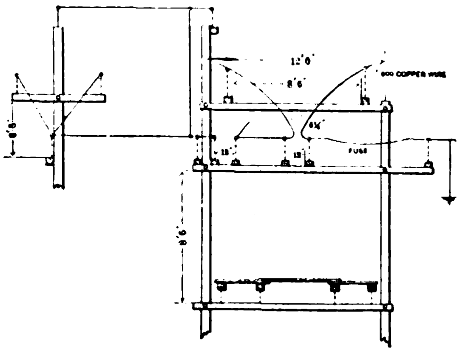

FIG. 1.
Horn Lightning Arrester, Joliette.

The Montreal lines run in a general northeasterly, southwesterly direction, parallel to the St. Lawrence River, and about 20 miles distant from it. The elevation of the power-house is about 200 feet above sea-level, that of the sub-station being nearly the same. Some 10 miles farther north and parallel to the transmission lines, the Laurentian Mountains bound the north side of the St. Lawrence Valley. In general, the country over which the lines pass is a flat farmland, but near the power-station the country is very rough.

The prevailing winds are westerly, and the general course of the electrical storms is parallel to the lines. The storm period extends from March to October. Nearly all the storms occur during the latter part of June, and in July, August and early in September. The storms are most severe during July and August. In the territory covered by the lines of the Shawinigan Company there occurs during each year about fifteen thunder storms. As these storms move along in an easterly direction and sometimes take days to cover the 100 miles, we have found that from June 25 to September 10, a storm is reported nearly every day from some part of the line. In general, however, there are not more than four or five severe storms during each year, and these storms are most severe in well defined localities. The discussion of our experiences with lightning will be simplified if these experiences during 1903, 1904 and 1905 are considered separately, year by year.

As stated above the only line in operation in 1903, was the No. 1 Montreal line. That line was protected by low-equivalent arresters at each end. During the summer of 1903, several disturbances occurred, which may be summarized as follows:

1. Poles splintered by heavy discharges.
2. In a few instances, insulators broken.
3. Flashes across the static-interrupter terminals.

4. Arcs on the transformer terminals.

5. Arcs inside the transformer cases at the top between adjacent leads.

6. Damage to apparatus caused by 3, 4 and 5.

7. Interruption to service, due usually to excessive voltage-drop, causing synchronous apparatus to fall out of step.

1. On several occasions poles were splintered. In most cases two or three poles were torn to pieces; the adjacent poles on both sides were less damaged, the damage decreasing as the distance increased from the point of disturbance. One of the worst cases recorded by us shows that five poles were torn to pieces, while ten poles on each side were somewhat splintered. This disturbance extended over a distance represented by 25 poles, or about 2,500 feet. This case, however, is exceptional, usually not more than one pole is badly damaged and a few of the nearby poles slightly splintered.

2. In only one or two instances were insulators broken; in each instance it was the top insulator. In these cases the breakage seemed due to the flashing over and consequent heating, as the insulator was not in any case punctured. In no case was an insulator so badly damaged as to need immediate replacing.

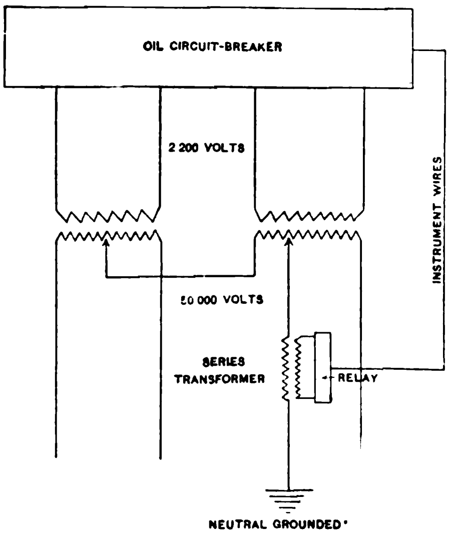

Fig. 3.—Transformer Connections.
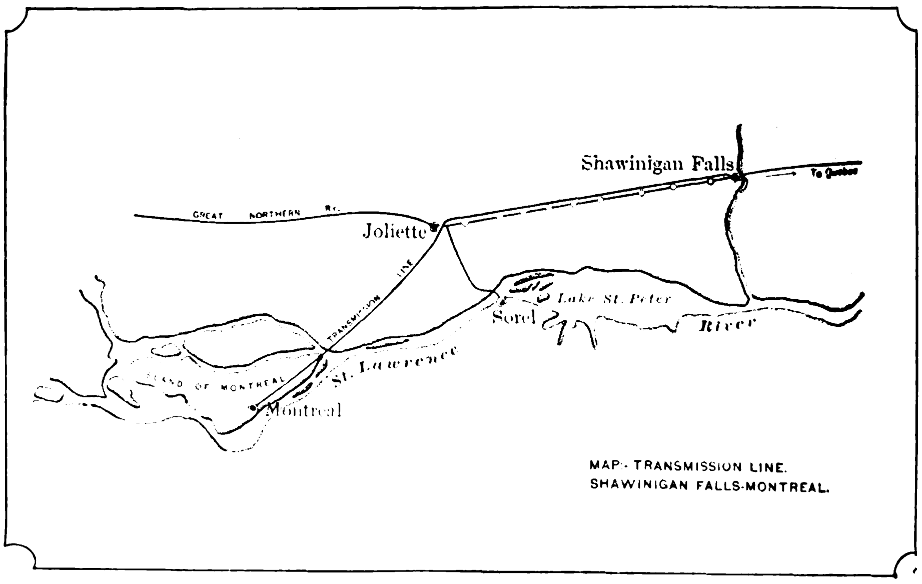
Note—Neutral point grounded through a series transformer and relay. Current in ground-wire, trips oil circuit-breakers.

3. At the same time that the poles were splintered on the line, there would be evidences of excessive potential in the stations. The most frequent occurrence was an arcing over on the terminals of the static-interrupters. In some cases this flash would reach across to an adjacent static-interrupter and establish a short circuit between the lines. In most cases, however, it was simply a flashing from the ends of the terminal to the case, or between the incoming and outgoing wires of a single static-interrupter, thereby short circuiting the reactance coil.

4. The arcs on the transformer terminals were more rare, only occurring when the static-interrupters were put out of service by the flashing over mentioned above.

In view of the above disturbances and damage it was decided to put in a type of horn lightning-arrester affording a low resistance path to ground, to depend on a fuse for the interruption of the short circuit which would occur if the horns did not break the arc, and to set these horns so, that only the heavier discharges would break them down. The horns were consequently adjusted to discharge at about 90,000 volts.

At the end of 1903, it was determined that the arresters installed were sufficient to meet the conditions caused by ordinary storms. They protected the line from abnormal rises of potential due to switching or short circuits; but in those cases when the lightning-stroke damaged poles on the line the rise of potential was so high and took place so rapidly that the arresters could not carry enough current to keep the potential of the line to within safe limits. The horns installed were especially designed to meet only the conditions which were not met by the standard arresters.



MAP - TRANSMISSION LINE.
SHAWINIGAN FALLS-MONTREAL.

In 1904 there were more than the usual number of storms. On the following dates the horns discharged:

Date.	Shawinigan.	Joliette.	Montreal.
July 11..	3 horns.	1 horn.	None.
Aug. 5..	2 "	3 horns.	"
Sept. 20.	2 "	2 "	"

One or two storms did not cause any disturbance.

The storm of July 11 was central near the power-station, and one pole about five miles distant was splintered. The Joliette horns discharged about an hour before the discharges took place at Shawinigan.

On August 5, the storm was central at Joliette. Both the horn arresters and the standard arresters discharged violently, the horns at Shawinigan discharging at the same time. There was evidently a rise of potential in the Joliette station, as one of the glass windows through which the wire enters the building was cracked, due to the flashing over which must have occurred. At the same time that this disturbance occurred in the station, some 25 poles about five miles away were splintered, a few of them very badly. No disturbance other than the discharge of the arresters occurred in the other stations. The service was not interrupted, a rather severe blow being felt, lasting only about a second.

On September 20, the storm was central about midway between Shawinigan and Joliette. Fifteen poles were struck. No excessive potentials were noticed in the stations, nor was the service interrupted.

During 1905 the number of storms was less than usual, but there were two very violent storms, both near Shawinigan. Poles on the No. 1 line were damaged. At various times during the summer the horns of both lines discharged, but it is noteworthy that the horns of the two lines did not discharge at the same time; that is, the two lines only about 100 feet apart would not be equally affected by lightning discharges.

The horn arresters on the No. 2 line were designed to take less current than those on the No. 1, as a resistance consisting of a mixture of glycerine and water was put in the ground connection; in parallel with this resistance was a horn-gap. During the first storms it was noticed that the resistance had "an equivalent spark-gap", greater than the horn, although the resistance was about 10,000 ohms, and the gap about 3 inches. The resistance was greatly decreased early in the summer by pushing the terminals closer together and the gap was slightly increased. After this was done the lightning discharge went through the resistance.

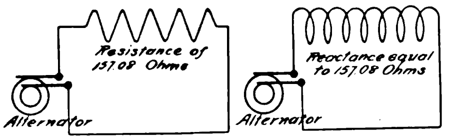
Another factor came into play in 1905. The two long-distance lines are operated in parallel on the low-tension sides at both ends. As stated previously, the neutral point of the transformer banks is grounded at Shawinigan. A series transformer was placed in the ground-wire leading from each bank of transformers, and an overload relay connected to this series transformer so that if any considerable amount of current flowed into the neutral the relay would open up the low-tension side of all of the transformers connected to that line. The operators in the Montreal terminal station were depended upon to separate the two lines in cases of trouble. By this means, a ground or heavy disturbance on one line would cut that line out of service. Our experience during the past year shows that this scheme works satisfactorily. To some extent, however, it masks the action of the lightning-arresters, as in case of heavy discharges over the horns the relay would cut off the line.

Summing up our experience with reference to the horns, I would say that we consider them a valuable addition to the standard equipment. Since the installation of the horn arresters, we have had no arcs in our station. No damage has been caused to our apparatus. No interruptions to our service have been caused directly by lightning. On the other hand, each time the horns discharged a more or less severe short circuit occurred, in no case, however, being severe enough to cause trouble or to cause our synchronous apparatus to fall out of step.

LIGHT, HEAT AND POWER PRINCIPLES.—VII.

BY NEWTON HARRISON, E. E.

Self-Induction and Resistance.—When the current is suddenly varied in a circuit the lines of force surrounding the circuit vary correspondingly and create within it self-induction. But this self-induction is able to produce an effect within the circuit equivalent to the presence of resistance, as far as the limitation of the flow of current is concerned with an alternating electromotive force. The name given to this effect has been variously styled spurious resistance, inductive resistance or reactance. It must be understood that the success of electric lighting and power distribution, as well as transmission, are dependent upon a proper consideration of the relationship existing between the self-induction, resistance and capacity of the circuits carrying alternating electrical energy. By this is meant, that the degree to which the angle of lag appears is a measure of the amount of useful power in the circuit. This inductive resistance arising in the circuit, through the variations in the current strength, is not an energy-wasting form of resistance. It simply suppresses the full manifestation of energy otherwise possible. The ohmic equivalent of it may be given by means of a simple calculation, $p \times L$, which takes into consideration the frequency with which the current alternates per second, and the self-induction. The exact values of these are given under the symbols of $p = 2 \times \pi \times f$ and $L =$ henries, in which $f =$ cycles per second, $\pi = 3.1416$, and L represents a definite quantity obtained by special calculation. Before L is calculated in detail, with respect to coils carrying a current, the value of reactance, as it is called, when caused by self-induction and frequency, will be shown in a specific case. The inductive reactance of a coil, for instance, in which a current passes alternating 100 times a second, and having a self-induction $L = .25$ henry, would be $2 \times \pi \times 100 \times .25 = 2 \times 3.1416 \times 100 \times .25 = 157.08$, representing the equivalent in ohms in the circuit. If the frequency were doubled the inductance reactance would be twice as much, or $2 \times 157.08 = 314.16$.



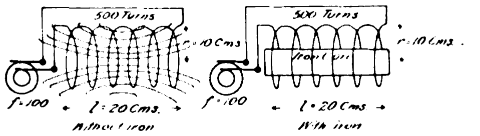
Resistance equivalent of inductive reactance.

TABLE BASED UPON THE INDUCTIVE REACTANCE $2\pi f L$.

Frequency.	Self-induction.	$2\pi f L$.	Ohms equivalent.
10	.1 henry	6.28 × 10×.1	6.28
20	.1 "	6.28 × 20×.1	12.56
30	.1 "	6.28 × 30×.1	18.84
40	1 "	6.28 × 40×.1	25.12
50	.1 "	6.28 × 50×.1	31.40
60	.1 "	6.28 × 60×.1	37.68
70	.1 "	6·28 × 70×·1	43·96
80	·1 "	6.28 × 80×.1	50.24
90	.1 "	6.28 × 90×.1	56.52
100	.1	6.28 × 100×.1	62.83

The above table shows the variations in reactance with systematic variations in the frequency. The ohmic equivalent of reactance, due to inductance, is thus shown to be increased if the frequency increases, and to decrease if the frequency decreases. The case above noted would be practically that of a coil of fixed self-induction, through which currents of an increasing frequency have passed.

Self-Induction of a Coil.—The calculation of the self-induction of a coil is simple enough to only require arithmetical treatment. The elements to be considered are those relating to the construction and core of any coil. When the coil has or has not iron in it as a core, the self-induction is less or greater in proportion to the permeability of the iron. The self-induction $L = 4\pi^2 r^2 n^2 \div l \times 10^9$ when the coil is not very thick and contains no iron. If there is an iron core, then $L = 4\pi^2 r^2 n^2 \mu \div l \times 10^9$, which is approximately true for the character of coils cited belonging to the class generally employed with fairly high frequencies on alternating current lines. In these two formulas, based upon the absolute system, $L =$ henries of inductance, $\pi = 3.1416$, $r =$ mean or average radius of coil in centimeters, $n =$ the number of turns of wire, and $l =$ length of coil in centimeters. The μ varies with the number of lines of force in the core or its degree of magnetization. In applying the formula the following case may be considered: A coil 20 centimeters long, whose average radius equals 10 centimeters, the number or turns being 500. According to the formula $L = 4\,(3.1416)^2 \times 10^2 \times 500^2 \div 20 \times 10^9 = 4 \times 3.1416 \times 3.1416 \times 100 \times 250{,}000 \div 20 \times 10^9 = 3{,}948 \times 25 \times 10^4 \div 2 \times 10^{10}$ equals, after canceling through, the total of .04935 or, what is called on the basis of $\frac{1}{1000}$ of a henry, being called a millihenry, 50 millihenries. These results may be developed with respect to a coil having iron in it, as mentioned with reference to the permeability μ. If in the case just noted the permeability is given as 500, then the result obtained, .04935 henries, will be multiplied by 500 and become $500 \times .04935 = 24.675$ henries. A table built up on this basis, showing the difference between a coil, with and without iron as a core, is given as follows:



Comparison of inductance of coil with and without iron.

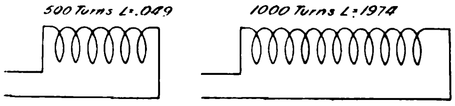
TABLE SHOWING THE INDUCTANCE WITH AND WITHOUT IRON AS A CORE.

Iron.	Per-mea-bility.	Turns.	Length in cms.	Radius in cms.	Induct-ance.
None	1	500	20	10	.04935
With	500	500	20	10	24.675

But another feature worth noting is that of the effect of the increase or decrease of the turns upon the inductance resulting. For instance, it is readily proven that the inductance varies as the square of the turns. In other words, if the turns are doubled the inductance becomes four times as great, as indicated in the following relative table of differences:

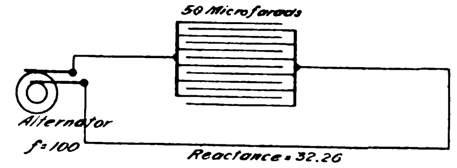
Turns.	Inductance.
1	1
2	4
3	9
4	16
5	25

The exact calculations would show the same result, based upon the fact that the turns are squared in the formula to get L. For instance, in the case given—that of a coil of 500 turns without iron as a core—when the turns are doubled the inductance ought to be four times as great as .04935, or 4 × .04935 = .19740. Calculating with 1,000 turns instead of 500 gives the following value: $L = 4\pi^2 r^2 n^2 \div 1 \times 10^9 = 39.48 \times 100 \times 1,000,000 \div 20 \times 10^9 = 39.48 \times 10^8 \div 2 \times 10^{10} = 19.74 \div 100 = .1974$. This verification can be readily carried out in any other case, thus developing a principle of importance in an industry utilizing variable currents in inductive circuits. *Principle*—The self-induction is proportional to the square of the turns. A further verification could be made by making the turns three times as great, or 1,500, and noting that the inductance resulting would be nine times as great. The coil of 500 turns, with a mean radius of 5 centimeters and a length of 20 centimeters, when used as a basis can become the foundation of a table in which the turns increase systematically. But it is evident that such a table would have to take into consideration the change in inductance, due to the change in the radius of the coil and perhaps of the length as well. But with this demonstration of the fact that self-induction can be calculated from the dimensions and conditions of a circuit, it becomes possible to refer to the reactance of a circuit due to its capacity.



Doubling the turns gives four times the inductance.

Capacity Reactance.—Instead of the capacity in a circuit acting to hold the current back, its effect is just the opposite; it makes the current lead. A condenser of sufficient microfarads capacity, when connected to an alternating source of electricity, brings into existence a new phenomenon, namely, that of the current entering the circuit in advance of the pressure. The reason for this is found in the electrostatic qualities of the condenser itself. It really represents greatly extended terminals of an alternating current circuit; as if the terminals were acting by electrostatic induction to obtain a charge. Being the circuit terminals in a sense, the condenser plates receive their electricity before the potential has reached its maximum value. The effect on a time basis is that of a charge in the condenser before the electromotive force has arrived. This presents the phenomenon of lead instead of lag, as is the case with the impeding effects of inductance. In ohmic equivalents the reactance of capacity may be found by means of the following formula: Capacity reactance = 1 ÷ 2 π f K, where π = 3.1416, f = frequency in cycles per second and K = capacity in farads of the system. For instance, if a circuit has a capacity of .000050 of a farad, equal to 50 microfarads, as ordinarily termed, and the current circulates back and forth at the rate of 100 times a second, the reactance valued in ohms would be 1 ÷ 2 × 3.1416 × 100 × .000050 = 1 ÷ 628.32 × .000050 = 1 ÷ .031 = 32.26. The idea presented here is to show that the reactance due to the capacity and frequency, as well as the capacity due to inductance and frequency, represent tangible values. This is important with reference to the considerations involved in the total effect of resistance, self-induction and capacity. This combination effect, as it may be called, is given the name of impedance.



Capacity reactance in a circuit.

Impedance.—All power transmission circuits are estimated with reference to the impedance. The impedance may be called the combination of reactance and resistance. It is generally expressed in the following form: Impedance =

$$\sqrt{\text{Resistance}^2 + (\text{Reactance})^2}.$$

But it is well known that the forms of reactance are due to inductance and capacity, whose net effects upon each other are such that where related in a certain manner they neutralize each other. For instance, if impedance is to be properly estimated, the formula must be written in such a manner that cognizance is taken of this fact. Impedance, therefore, would be

$$\sqrt{\text{Resistance}^2 + (\text{inductance reactance} - \text{capacity reactance})^2}$$

in its exact form and value. Where the inductance predominates to such an extent that the capacity may be neglected, the formula for impedance becomes

$$\sqrt{R^2 + p^2 L^2.}$$

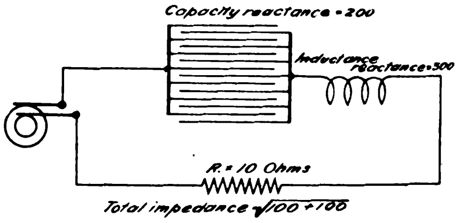
But if the capacity reactance is sufficiently large to require valuation, then the impedance becomes

$$\sqrt{R^2 + \left(p\ L - \frac{1}{pK}\right)^2}$$

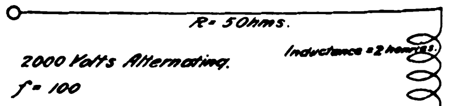
This merely represents an instance of where the capacity reactance is subtracted from the inductance reactance to get the correct impedance. The previous cases could be used as examples, but the following will also serve to illustrate the principle involved. If the resistance in ohms in a circuit is 10, and the inductance resistance 300, then with a capacity reactance of 200, the impedance would equal the

$$\sqrt{10^2 + (300 - 200)^2} = \sqrt{10,100} = 100$$

plus. The resistance effect in this case is almost negligible, for the reason that the reactance operating when squared gives 10,000; whereas the resistance of 10 only gives 100 when squared. An instance of this kind is one in which the resistance plays very little part in the transmission of power. As an example, the following may be given as a case where inductance is the chief factor. A 2,000 volt line has a resistance of 5 ohms, and carries a current of 100 cycles a second with an inductance of 2 henries. The impedance



Impedance due to resistance, self-induction and capacity.



R= 5Ohms.
Inductance =2 henries.
2000 Volts Alternating.
f= 100
Impedance and reactance practically equal to 1051 in ohmic equivalents.

When resistance is low it is negligible compared to the reactance.

therefore is the square root of $5^2 + (2 \times 3.1416 \times 100 \times 2)^2 = 25 + 1,117,249$; which clearly shows how negligible a quantity the line resistance becomes when much inductance is present. The reactance is practically the entire impedance representing the figures 1,057 in ohmic equivalents. On this basis the current in the line would equal 2,000 volts ÷ 1,057, or practically only 2 amperes. The new formula thus appearing for use in connection with this state of affairs would be $C = E \div \sqrt{R^2 + p^2 L^2}$ for the value of the amperes.

Light and Power Problems.—The light and power problems are those which consider efficient power delivery as well as efficient light production. The neglect of circuit conditions is no worse than the disregard of the best means of producing light.

For instance, the expenditure of 1,000 watts for lighting really means the expenditure of more, because of the losses in distribution. It is difficult to grasp the nature of many of these problems, unless the effort is made with the backing of a certain amount of technical knowledge. For this reason the resume preceding these remarks has been made with the intent of presenting certain facts bearing upon the average case. No lines can be strung any great distance, or buried underground, which do not represent cases of the presence of inductance and capacity. The degree to which each are present is largely a matter of the make-up or configuration of the system. Capacity is dependent upon the nearness of one conductor to another, as well as the nature of the dielectric used as insulation. Inductance is dependent upon the number of interlinkings taking place between the conductors respectively and the lines of force. It is thus evident, in the consideration of the conditions existing in light, heat and power problems, that a knowledge of the values of inductance, reactance and capacity, reactance is absolutely essential if a true insight into circuit conditions is desired.

Unless this is done the impedance will not be known at its true value. The current that is to be sent through a circuit will be impeded unduly, and the entire volume of power delivered is apt to be far below the value anticipated. In systems of power transmission and distribution the line losses are generally estimated at a certain percentage of the whole power. The design of the conductor to meet these conditions is, therefore, imperative, if intelligently pursued along the lines indicated.

THE INFLUENCE OF ELECTRICITY ON POWER ENGINEERING.*

BY W. B. ESSON.

The early seventies saw the inventions of Gramme and Von Hefner Alteck and the beginning of the electric lighting era. The first of Gramme's dynamos was brought to London in 1873, but needless to say it little resembled its progeny. Six years before Gramme obtained his first patent Pacinotti had illustrated and described in the "Nuova Cimento" the remarkable machine of his invention, and though this probably embodied in crude form all the elements of Gramme's dynamo, it required the mechanical genius of Gramme to convert into a practical machine what had been till his time a scientific toy. About the same period the Von Hefner Alteneck machine was being developed in Germany, but the early designs of both types were flimsy and built on lines adopted by mechanicians and instrument makers rather than on engineering lines. Soon the designing passed into the hands of engineers, and the flimsiness of the earlier patterns disappeared. From these early days till now progress has been continuous. In 25 years the size of electric generators has increased from 5 hp. to 5,000 hp., from the machines which fed the Jablochkoff candles in the Avenue de l'Opera in Paris to the magnificent triumph of engineering realized in the generators at Niagara.

It was not until 1880 that the first incandescent lamp factory was started on a commercial basis.

From 1880 onwards, power transmission made progress. Arc lighting work had taught manufacturers how to make machines for higher pressures, and the demand consequent on the invention of the incandescent lamp gave the necessary stimulus to development.

There was no such thing as transmission of power in the sense that we now understand it until the electric motor made its appearance.

About 1889, engineers on the Continent were faced with a very important problem. They saw in their waterfalls thousands of horse power running to waste. They knew that by adopting electric transmission this power could be utilized and distributed to great advantage amongst manufacturers scattered over a wide area, but they also recognized that success could only be obtained by the use of a pressure considerably higher than the 2,000 or 3,000 volts then in use. The problem required a considerable amount of study, the position being: For alternating currents, pressure all right, but no motor available; for continuous currents, motors available, but pressure not high enough. As the supply of power was the leading idea, the system which possessed the motor had to be chosen, and continuous current was consequently adopted, with the brilliant device, however, of joining up all the motors in series and spreading the high pressure over the lot, while connecting the generators in series to keep down the pressure on the commutators of individual machines. In this system the current is kept constant, the pressure varying according to requirements, and at the date I am speaking of it does not appear that there was any other way of providing a general power supply. It says much for the engineering of the installations on this system, that they are in most successful working to-day, and what is more, they are being added to in competition with the three-phase system.

Now a system showing such strong vitality, though working on what nine-tenths of our engineers would call antiquated lines, cannot be dismissed in a sentence. The facts are that the system is going ahead in the face of the three-phase alternating system and is successful on a scale commensurate with many of the larger three-phase installations. The Americans say that the success of such a system would be impossible in their country, because the motors would not get there the careful and skilled attention given to them on the Continent. This may be so, but with a large plant and sub-stations the objection need not hold. In any case it is certain that every engineer will look forward with the greatest interest to the completion of the large scheme now in progress.

It was at the Frankfort Exhibition of 1891 that the problem of long-distance transmission was successfully solved. A tremendous impetus was given to power transmission in Europe, and soon a large number of installations were working on the new system, transmitting power to distances up to about 15 miles, at pressures in the vicinity of 5,000 volts or so.

It was not until 1897 that any increase over the Frankfort pressure was made, but in that year the South Californian Power Company transmitted power over 80 miles at 33,000 volts. Several plants were installed at this pressure with the object of finding out whether a still higher voltage could not be successfully employed. These experiments culminated in the Telluride Company adopting, in 1893, a pressure of 40,000 volts for its Provo transmission, and at the present time there are several installations in the States working at this pressure. The Shawinigan Water & Power Company is operating over a line 84 miles long with 53,000 volts. The Washington Power Company, the California Gas & Electric Company, and the Guanajuato Power & Electric Company are all operating at 60,000 volts, while the Kern River Power Company is busy on a line on which the pressure will reach 67,500 volts. This is for the time being the highest pressure in the world, but two companies are making provision for their apparatus to be capable of working at 80,000 volts, so that whenever suitable methods of insulation for this pressure are devised they will be able to adopt it.

---

*Abstract of the presidential address to the Civil and Mechanical Engineers' Society, delivered in England October 5, 1905.

In Europe the pressure on transmission lines does not rule high. The distances are not great and under these circumstances it is preferred to keep the line pressure down to a figure which is possible to the generator armatures and does not require the use of step-up transformers. A most interesting example of a power installation in the Far East is furnished by the Mysore transmission of 4,000 hp. from the Cauvery River Falls to the Kolar goldfield, a distance of 92 miles, at 30,000 volts. A scheme which the Scotch Water Power Syndicate have in view is the transmission of 5,000 hp. to the Vale of Leven from a hydro-electric power station, 22 miles distant, supplied with water from Loch Sloy, which is situated 750 feet or so above Loch Lomond. Here the pressure proposed on the overhead transmission line is 40,000 volts. But the scheme is at present in the air and whether the conductors will ever get there I would not like to say.

Unless the power transmitted is very large the lower the pressure the better, provided that it is high enough to allow of the transmission being carried out economically. It would be folly to assert that there are no greater risks with the higher pressures, for, as a matter of fact, with pressures of 40,000, to 60,000 volts "the highest intelligence vigilance and excellence must be employed to avoid accident and insure success." These pressures are not to be used indiscriminately or when they can be avoided. A large number of plants are operating at pressures between ten and twenty thousand volts, and of these it may be said that the overhead lines give very little trouble. The latter figure represents a voltage which can be produced in the armatures of machines of moderate size without difficulty, so this pressure may be considered a limit below which step-up transformers may be dispensed with. When we get much above this we enter a zone where we begin to experience the line troubles which very high pressures bring, without obtaining all the advantages they confer. It is very questionable, therefore, whether there should be any halting place between twenty and forty thousand volts. At thirty-three thousand volts Dr. Perrine tells us that the special difficulties due to capacity, insulator size, erratic lightning arrester effects and switching begin to make themselves seriously felt, and it is just as well, if we have to re-design the apparatus with special reference to these difficulties, that we carry the pressure to the other extreme of the zone referred to, and so get the full return for our trouble. If pressures are ever standardized, the figures for the standards will be probably 20, 40, 60 and 80 kilovolts.

With pressures of the order of forty thousand volts, quite a new set of phenomena is brought to our notice. In the first place, the insulators, in order to prevent flashing over to the supports, must be very much larger and an increase of pressure from twenty to forty thousand volts necessitates their diameter being increased by 50 per cent. or more. A usual size of insulator for the former pressure is 6 inches diameter, while the latter should not be less than from 9 to 10 inches, with the addition of at least one intermediate bell between the outside dome and the inside cup. When these high pressures are used the phenomenon of brush discharge has to be provided against. This results from the breakdown of the air as an insulator, owing to electrostatic strain set up in the space between the wires, and it was very thoroughly investigated by several leading engineers in America in 1893. Their experiments showed that while the loss of power due to this cause at forty to fifty thousand volts was, with the usual line construction, inconsiderable, after the higher figure was reached the loss increased rapidly. Prof. Ayrton has lately worked out the distance wires of different diameters have to be placed apart to insure that with certain pressures there shall be no brush discharge. The cure of the evil is of course to keep the wires far enough apart and keep them large enough in diameter; for it is common knowledge that in the vicinity of a sharp point or a sharp edge less pressure is required to break the air down than in the vicinity of a knob or well-rounded edge. A thin wire presents along its whole length a comparatively sharp edge, and while with wires of one-tenth inch diameter forty thousand volts will discharge through about 10 feet, if the wire is one-fifth inch diameter discharge will only take place when the distance between the wires has been reduced to 15 inches. As it is usual to space the wires on a forty thousand volt line about 48 inches apart, and as in no lines requiring such high transmission voltage, are wires likely to be less than one-fourth inch in diameter, it will be seen that there need be no loss from this cause. But there is enough trouble with switches, lightning arresters and higher pressure surges in the line without brush discharge.

It is not the high pressure that makes the trouble last mentioned, indeed raising the pressure reduces surging, since the current is reduced with the increased pressure. Experience has shown that if a large amount of power is transmitted it is easier to operate lines at a pressure of sixty thousand volts than at a pressure of thirty thousand volts, because in the former case the current flowing is only about half. Suppose we are transmitting 5,000 hp. to a distance of 50 miles at thirty thousand volts. Roughly, the current in each wire will be 80 amperes, and it is possible that if this be suddenly interrupted the surge pressure would rise to twenty thousand volts.

There is no hard and fast rule for pressures to be used, but 1,000 volts per mile is recognized as good practice. This is subject to limitation on the one hand by the highest pressures of which we have commercial experience, and, on the other hand, by the condition that the current in any wire shall not be excessive, a point which has just been dealt with. According to Mr. C. F. Scott, a distance in miles equal to three times the number of thousands of volts may be covered without incurring an excessive annual charge per horse power for copper. But the solution to all engineering problems lies in compromising, and the pressure is eventually settled by striking a balance between the cost and the risks undertaken.

Up to the present I have referred to hydro-electric plants only, and it is not easy to estimate the total of the water power which has been utilized all over the world by their erection. I believe I am well within the mark by placing the total capacity of the hydro-electric power houses at work and under construction on the American Continent alone at a million hp. In Italy, Lombardy alone accounts for 88,000 hp. in hydro-electric power houses at work and under construction, while Switzerland, the home of hydro-electrics, accounts for 220,000 hp. Taking the whole world, the water-power utilized in the hydro-electric stations must be somewhere between a million and a half and two millions of horse power, a vast force, the greater part of which might have run to waste for all time had it not been for the invention of the dynamo.

All of these schemes cannot be placed in the same category. Cases are numerous in which electricity is employed merely as a means whereby the power of water can be conveniently parcelled out to various industrial undertakings in the immediate neighborhood. Such cases furnish an example of power distribution rather than of power transmission.

Needless to say, turbine construction has been influenced to a very large extent by electric power development. The design of turbines has not received much study in England, possibly because here the field of their usefulness is narrow. On the other hand, the subject has been studied exhaustively on the Continent, and it is to books written in another language that we must go for our information.

But if we are backward with respect to water turbines, we make up for this as regards the steam turbine, for if Britain is not exactly the birthplace of the latter, it is the country which has seen its greatest development. To-day there are 600,000 hp. of turbines of the Parsons type at work, and in 21 years the machine has grown from a 10 hp. infant to a 10,000 hp. giant. When it is remembered that the great success of the turbine has been due to the ability, energy and enthusiasm of one man, it is felt that he deserves the greatest and best rewards that engineering has to offer.

I have not touched upon that department of power engineering which concerns itself with railways. It is only 24 years since the first commercial railway was laid down, and to-day the capital invested in street railway undertakings is something in the vicinity of $1,000,000,000.

Brooklyn Rapid Transit's New Chief Engineer.

W. S. Menden has been appointed chief engineer of the Brooklyn Rapid Transit Company in place of Eugene Klapp, who resigned to enter business with W. B. Parsons. Mr. Menden was chief engineer and general superintendent of the Metropolitan Elevated Railroad Company in Chicago.

Edison Electric Lamp Patent Decision.

In Newark, N. J., last week, Judge Cross, of the United States District Court, dismissed the contempt proceedings brought against James McLaren, of Newark, by the Edison General Electric Company. Mr. McLaren was charged with infringing the Edison electric lamp patents, and has been successful in his contention that his process is different from that of the Edison Company.

Electrical Power in Potteries.

The owners of the potteries near Stockholm, Sweden, have been experimenting with electrical power. The results show that as compared with steam electricity is cheaper, handier and quite as efficient.

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until November 21 for furnishing Eastern Navy Yards with the following electrical material: Schedule 214, arc lamps; schedule 215, steel conduit, lighting wire; schedule 218, motors, armatures, lamp holders, incandescent lamps, cable, miscellaneous electrical supplies, electric soldering irons; schedule 219, Grimshaw tape. Blank proposals and specifications can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington.

ELECTRICAL PATENT RECORD

LETTERS PATENT ISSUED OCT. 31, 1905.

Electric Railways and Appliances.

802,993. Trolley-Wheel Bearing. Robert Kissinger, Columbus, O., assignor of one-half to S.B. Hartman, same place. Filed March 27, 1905.

803,020. Controller for Electric Cars. Francis A. Roche and Francis J. Roche, Somerville, Mass. Filed March 15, 1905.

803,208. Trolley-Catcher. Warren W. Annable, Grand Rapids, Mich., assignor of one-half to J. Watson Fitzgerald, same place. Filed March 31, 1905.

803,210. Trolley-Retrieving Device. Henry B. Clarke, Chicago, Ill. Filed Jan 16, 1905.

803,214. Controlling System for Railway Vehicles and Trains. John J. Crouse, New York City, asssignor, by mesne assignments, to the Westinghouse Electric & Manufacturing Company. Filed Jan. 22, 1903.

803,215. Overhead Structure for Electric Railways. Harry P. Davis and Theodore Varney, Pittsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company. Filed Oct. 19, 1904.

803,216. Suspension Device for Trolley-Conductors. Harry P. Davis and Theodore Varney, Pittsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company. Filed Jan. 17, 1905.

03,252. Trolley for Electrically Operated Vehicles Norman W. Storer, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Feb. 15, 1905.

803,365. Electric Railway. Maurice C. Rypinski, Schenectady, N. Y., assignor to the General Electric Company. Filed March 31, 1902.

803,502. Railway Signal System. James C. Mock, Detroit, Mich. Filed Jan. 11, 1902.

Electric Lights and Appliances.

803,245. Plug or Connection for Electric-Light Line-Wires. Charles P. Parnell, New York City, assignor of one-half to Harris M. Fletcher, same place. Filed April 19, 1904.

803,246. Electric-Lamp Socket. Charles P. Parnell, New York City, assignor of one-half to Harris M. Fletcher, same place. Filed May 18, 1904.

803,423. Electric-Lamp Socket. Norman Marshall; Newton, Mass., assignor, by mesne assignments, to the General Electric Company. Filed Dec. 24, 1900.

Electrical Machinery and Apparatus.

802,967. Method of Bonding Electric Conductors. Harold P. Brown, Montclair, N. J. Filed Jan. 3, 1905.

802,994. Terminal-Connector for Electric Conductors. John H. Kliegl and Anton T. Kliegl, New York City. Filed Dec. 8, 1904.

803,136. Electric Switch. John J. Ruddick, Newton, Mass., assignor to the United States Electric Signal Company. Filed Nov. 27, 1903.

803,209. Control System for Electric Motors. Ralph E. Bates, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Feb. 1, 1905.

803,213. Alternating-Current System of Control. Frank Conrad, Edgewood Park, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 3, 1905.

803,233. Electric-Control System. Henry D. James, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 3, 1905.

803,253-254. Electric Regulator or Controller and Method of Regulating Alternating-Current Electromotive Force. Harve R. Stuart, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 26, 1903. Renewed Oct. 25, 1904.

803,378. Control of Electric Elevators. George A. P. Weymouth, Melbourne, Victoria, Australia. Filed April 3, 1905.

803,414. Remote-Control Regulator. John L. Hall and William C. Yates, Schenectady, N. Y., assignors to the General Electric Company. Filed March 20, 1905.

803,442. Apparatus for Short-Circuiting Turns in Armature Coils. John F. Shoemaker, Madison, Wis. Filed April 13, 1905.

803,462. Alternating-Current-Motor Control. Charles E. Barry, Schenectady, N. Y., assignor to the General Electric Company. Filed June 24, 1904.

803,486. Magnetically-Operated Switch. George H. Hill, Schenectady, N. Y., assignor to the General Electric Company. Filed June 18, 1904.

Telephones and Telephone Apparatus

803,199-513. Space Telephony. John S. Stone, Cambridge, Mass. Original application filed June 20, 1905. Divided and last application filed June 29, 1905.

Miscellaneous.

802,981. Wireless Signaling Apparatus. Lee De Forest, New York City. Filed Dec. 10, 1902.

803,010. Insulator, Elmer P. Morris, East Orange, N. J. Filed June 6, 1904.

803,107-110. Transmission of Electric Currents. Isidor Kitsee, Philadelphia, Pa. Filed May 20 and Nov. 28, 1904.

803,108-109-111-112. Electric Transmission of Intelligence and Transmission of Intelligence with the Aid of Electric Energy. Isidor Kitsee, Philadelphia, Pa. First application filed June 24, 1904. Last application filed April 10, 1905.

803,147 Electric Furnace. Edwin Appleby, Chicago, Ill. Filed Jan. 28, 1905.

803,180. Means for Producing High-Potential Electrical Discharges. Oliver J. Lodge, Birmingham, England. Filed Oct. 10, 1904.

803,237. Electric Relay. Isidor Kitsee, Philadelphia, Pa. Filed May 3, 1905.

803,263. Electrolytic Cell. Henry S. Anderson, El Paso, Tex. Filed June 21, 1905.

803,410. Electromagnet. Arthur C. Eastwood. Cleveland, O. Filed April 1, 1904.

803,451-452-453. Rheostat. George E. Stevens, Lynn, Mass., assignor to the General Electric Company. Filed Oct. 1 and 12, 1904.

803,493. Long-Distance Electric Circuit. Mark S. Lewis, Medford, Mass., assignor of one-third to George F. Woodley, Providence, R. I. Filed May 4, 1905.

THE TELEPHONE WORLD.

Telephone Company to Double Its Capacity.

Plans of the United States Independent Telephone Company as outlined from St. Louis, Mo., include the doubling of the capacity of the Stromberg-Carlson Telephone Manufacturing Company's plant in Rochester, N. Y. At present it employs 2,500 people, and is capitalized at $6,000,000. It is said to be the intention of the United States Independent Telephone Company to increase the capitalization of the Rochester Company and to raise the force of workmen to 5,000.

A plant similar to that in Rochester is to be built in St. Louis with a capacity equal to that of the former plant at present. The company in Rochester would provide New York and the eastern section of the country with supplies, while that at St. Louis would supply the companies in that section.

Will Place Wires Underground.

The stockholders of the York, Pa., Telephone Company at a recent meeting voted unanimously to increase the capital stock of the corporation from $200,000 to $500,000 for the purpose of placing the wires of the company's system underground, making important rural extensions to the system, and adding general improvements. Charles H. Lidlie, electrical engineer of St. Louis, Mo., has been engaged to prepare plans for a conduit system for the county.

The North Vancouver telephone system is to be installed within six months. Some uncertainty having existed in relation to the exact time when the system was to be established, Superintendent H. W. Kent, of the British Columbia Telephone Company, states that the telephone company was prepared to go on with the work just as soon as the necessary cable could be procured. There was no doubt that the material would be forthcoming within a few months, and he said that the residents across the Inlet could rely on being furnished with the convenience of telephone communication within a period of six months at the most.

The charter of the South Texas Telephone Company, which is to take over several long-distance telephone lines and local exchanges, has been filed in the office of the Secretary of State. It has a capital stock of $400,000, and the principal office is in Austin. The incorporators are J. A. Quisenberry, of Danville, Ky.; A. E. Schaffer, of Wapakoneta, O.; W. R. Stephens, F. C. Smith, of San Antonio, and J. Boynton, of Waco.

The Texas Independent Telephone Association is now convening in Dallas, holding a two days' session, November 7 and 8. The officers of the association are as follows: President, E. W. Dunaway; secretary, J. B. Earle.

The Brighton, Ia., telephone exchange, formerly owned by G. W. Smith, has been purchased by the Brighton Mutual Telephone Company.

The Stark County, O., Telephone Company is about to spend $173,000 in improvements in Canton and Alliance.

Nebraska Meeting of Independents.

November 11 is the date set for the meeting of the Nebraska Indpendent Telephone Association. It will be held in Hastings in the new building of the Hastings Independent Telephone Company. The purpose of holding the meeting in that city is to allow the members to inspect the new exchange, which, though not yet completed, is said to be noted as a model exchange. W. E. Bell, of York, is president of the association, and F. E. Ebersole, manager of the Lincoln Telephone Company, is secretary.

Telephone Bids.

On November 21 the Bureau of Supplies and Accounts will open bids for furnishing the New York Navy Yard for the naval station at Guantanamo Bay, Cuba, 60 telephones complete and a quantity of porcelain cleats and telephone cable, embraced in schedule 223. Blank proposals and detailed information respecting the above requirements can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington, D. C.

A special meeting of the stockholders of the National Telephone Company of Wheeling, W. Va., has been called by Secretary Will C. Handlan for the purpose of considering a resolution authorizing an increase in the capital stock of the company, and also a resolution authorizing the issuing of bonds, and providing for the retiring of outstanding bonds. The increase of the capital stock is contemplated to enable it to branch out and prosecute the various extensions that have been under consideration for some time.

A second telephone system in Detroit, Mich., is opposed by the board of directors of the board of commerce. They would be glad to have the Independent telephones of the State connected with Detroit, but not through the medium of a second system, which would only result in lasting confusion and would mean more poles and wires and increase the danger from contact with deadly currents. Detroit, the directors say, should be distinguished among American cities for attractiveness, and in time all poles and overhead wires should be eliminated. Further, in case of municipal ownership being brought about, the city would have two systems instead of one to buy.

The work of extending the telephone system in and about Danbury, Conn., is progressing steadily. With the completion of the line in Beaver Brook and Great Plain work has been commenced on the setting of the poles for the new line to Lake Kenosia by way of Lake avenue.

The Steinauer, Neb., Telephone Company, incorporated in 1900, recently amended its articles of incorporation, increasing its capital stock from $3,000 to $25,000.

The New Ulm, Minn., Telephone Company lately increased its capital stock from $50,000 to $100,000.

The Steuben County Electric Telephone Company, located in Angola, Ind., has increased its capital stock from $5,000 to $100,000.

Two Systems to Unite.

The death knell of telephone competition in Kenosha, Wis., was sounded a short time ago, when articles were filed at Madison, for the incorporation of the Kenosha Home Telephone Company. The incorporators are Alonzo Burt, of Milwaukee; James Cavanagh and Frank Slosson, of Kenosha. Neither of the Kenosha men are interested financially in the company. The capital stock of the company is $175,000, and it is understood that seven of the nine directors will be Kenosha men. The new company will shortly take over the plants of the Wisconsin Telephone Company and Citizen's Telephone Company in Kenosha and the two will be united. The officers of the new company have not as yet been elected.

The Providence, R. I., Telephone Company has begun the work of laying conduits in the streets of the Pier, preparatory to placing a part of its wires underground in accordance with the terms of the agreement by which the company received an exclusive franchise to the streets of the Pier from the town council last winter. By that agreement the company was to place a certain amount of its wires underground within one year from the date of the franchise and the work is now underway and will probably be completed in about six weeks.

Within a short time it is expected that telephone connection with Los Angeles, Santa Ana, Cal., and other cities in that vicinity, will have been established by means of the Home Telephone Company's system. Two wires are being strung, one to give through service to Los Angeles, and the other, which will also be a through one, will carry the way exchanges.

A local telephone exchange is being built by the Wisconsin Telephone Company at North Milwaukee, like those at West Allis and Wauwatosa. There will be 100 subscribers at the start. No toll charge will be made to North Milwaukee as in the past. Persons within one and one-half miles will be given telephone rates the same as those in Milwaukee.

The American Automatic Telephone Company has been incorporated at Albany, N. Y. Its principal offices are in Rochester, and it is planned to erect a factory for the construction of a device to do away with the "hello" girl. The company is capitalized at $1,500,000. Charles L. Goodrum and J. W. Lattig are the inventors of the device.

The Nebraska Telephone Company will erect a large warehouse and workshop in Omaha. It is the purpose of the company to begin work on this building at the earliest possible moment. as it is needed at once.

With a capital stock of $5,000, the Blooming Grove, Tex., Telephone Company received its charter. The incorporators are J. H. Jones, T. T. Grady and J. B. Germany.

The Jasper County Telephone Company has made connection from Montrose to Newton, Miss. The line will at once be extended south by the way of Louin to Bay Springs.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albuquerque, N. M.—The Gallup electric light plant, owned by Gregory Page, has been sold to E. C. Allen, formerly manager of the electric light company of this city. The terms of the sale have not been made public, but it is learned that the consideration is about $25,000. It is also learned that the First National Bank is interested in the purchase.

Anaheim, Cal.—An election will be held here November 11, for the purpose of voting on a bond issue of over $50,000 for improving the city's electric light plant, and for extending the water system.

Bamberg, S. C.—At a recent election to decide the question of issuing $15,000 of municipal bonds for the purpose of erecting an electric light plant here, only one vote was cast against the proposition.

Burt, Ia.—The citizens have voted for an electric light plant and waterworks system.

Collierville, Tenn.—R. C. Kinner, of Jackson, Miss., is engineer in charge of the construction of the municipal electric light plant, which is to be equipped for 1,000 16-cp. incandescent lamps and 36 arc lamps. Dr. E. K. Leake, mayor.

Green Bay, Wis.—A deal has been closed by which Sinclair Mainland, of this city, and William Mainland, of Oshkosh, have disposed of their gas and electric plants at Fargo, N. D., to Paul Doty, vice-president and general manager of the St. Paul Gas Light Company, George H. Prince, of St. Paul, and J. W. Smith, of Fargo.

Lawrenceburg, Tenn.—The proposition to issue $25,000 in bonds to establish waterworks and an electric light system was recently carried.

Lockport, N. Y.—The Lockport Gas & Electric Light Company has been granted a franchise by the common council for light, heat, power and refrigerator purposes on all the streets of the city.

Lyon Falls, N. Y.—This place is soon to have electric lights.

Monroe, Mich.—At a special session of the council it was decided to hold an election November 14 to submit to the voters the proposition of bonding the city for $20,000 for a new and up-to-date lighting plant.

New Brunswick. N. J.—A big plant to manufacture an improved electric arc lamp is to be built in this city by the Scott Company.

Oswego, N. Y.—Representatives connected with the proposed new electric light company are circulating among business houses and manufacturing establishments, making contracts with the same at a specified amount, the contracts to commence next spring John C. Knight will be manager of the new power plant.

Oyster Bay, N. Y.—After a fight that has lasted years, the Nassau Electric Light & Power Company has absorbed the Oyster Bay Light & Power Company, and will take possession of the latter's plant here in a few days. Interested in the Nassau company are Edwin D. Morgan, Clarence H. Mackay, Percy Chubb and other well-known men.

Salem, Mass.—An effort will be made to establish a municipal electric lighting plant here. Councilman McSweeney is in favor of such a plant.

Tallapoosa, Ga.—The proposition to issue $10,000 in bonds for the erection of a new and up-to-date electric light plant was lately carried.

West Albany, N. Y.—The streets of this village will soon be lighted by electricity.

Williamston, N. C.—This town wants to correspond with electric companies relative to the installation of an electric light plant. Address S. J. Everett, secretary of the Business Men's Association.

STREET RAILWAYS.

Athens, Ga.—The Secretary of State has granted an amendment to the charter of the Athens Electric Railway Company, under which it will increase its capital stock from $100,000 to $125,000, the additional amount to be in preferred stock.

Atlanta, Ga.—The Atlanta & Carolina Railway Company, which has perfected plans for the construction of an electric trolley line from this city to Anderson, S. C., running through Gwinnett, Jackson, Banks, Franklin and other counties, was recently granted an amendment to its charter by Secretary of State Phil Cook, under which it will be permitted to run also through Rockdale County and through Conyers by way of Lithonia in De Kalb. Hon. John R. Hosch, of Hoschton, Jackson County, who is largely interested in this line, stated that the company had about made its final arrangements and would within the next few weeks begin the construction of its line.

Atlantic City, N. J.—The city council has granted the Central Passenger Railway Company a franchise to build a trolley line over the west side district to Marmora avenue and Pleasure Bay. Eventually the line will cross Beach thoroughfare at that point and run directly to the mainland.

Bay City, Mich.—Edgar H. Whitcomb is president of the Detroit-Bay City Traction & Electric Company, which will build the electric railroad from this city to Detroit.

Boonville, Ind.—It is the intention of the Evansville & Newburg Electric Company to extend its lines from this city, to which point it is now building up through Lynnville in Warrick County, thence through Oakland City.

Buffalo, N. Y.—At a meeting of the State Railroad Commission on December 5 the application of the Buffalo & Rochester Traction Company for a certificate of necessity will be considered. The company succeeds the Buffalo & Rochester Electric Railway Company, now in process of voluntary dissolution.

Butler, Pa.—The work of grading the new trolley line is now in sight of this city.

Henrietta, N. Y—This town has granted a franchise to the Caledonia, Scottsville & Rochester Electric Railroad.

Hoboken, N. J.—K. B. Conger, secretary of the Hudson Street Railway Company, states that property owners everywhere are signing consents for the new trolley system that his company is planning to install in Hudson County.

Marysville, O.—Indications show that the Columbus, Urbana & Western Electric Road, which is in the hands of the Schoepf Syndicate, will be built through Union County,

Mattoon, Ill.—The Secretary of State has issued a license to incorporate the Decatur, Sullivan & Mattoon Transit Company. The principal office is to be here The capital stock is nominally $25,000. It is proposed to construct an electric railroad from this city in a northwesterly direction to Decatur. The incorporators and first board of directors are R. J. M. Clokey and J. H. Culver, Decatur; George B. Spitzler, Mount Zion; John R. Hamilton and Edward C. Craig, Mattoon.

Milwaukee, Wis.—The Milwaukee Northern Railroad Company, incorporated with a capital of $100,000, by John E. Uselding, of Port Washington, and John M. Seaman, of Sheboygan, intends to build an interurban electric line from Sheboygan to this city.

Salt Lake City, Utah.—The county commissioners have passed an ordinance granting to J. F. McCarron a franchise to operate an electric railway in Weber County. Although the franchise affects the county alone, it is understood that the proposed line is to become a part of the Eccles roads, connecting at the southern limits of the city with the line of the Ogden Rapid Transit Company's tracks, and at the northern limits of the city with the tracks of the Ogden & Northwestern Line, which now extend to the Hot Springs.

Wappingers Falls, N. Y.—It is claimed that a trolley line will be constructed early in the spring to connect this place with Fishkill.

Winona, Ind.—The trolley line that was to have been built from Wabash to this city has been proposed for a different route. Instead of Wabash being one of the terminal points, the line will be operated between Peru and this city.

POWER PLANTS.

Salt Lake City, Utah.—Irwin E. Pratt, secretary of the Blue Bench Co-operative Water Company, has made application in the State Engineer's office for the appropriation of power to be taken from the Green River system in Wasatch County. The diverting channel is to be 36,500 feet in length, 18 feet in width and 4 feet in depth.

Woodstock, Ala.—Smith & Weaver want information as to the cost, etc., of a small power plant to operate a barrel factory.

Walla Walla, Wash.—The Northwestern Gas & Electric Company has increased its capital from $15,000 to $1,000,000. It is hinted that the company has plans under way for the construction of another huge power plant.

BIDS WANTED.

Alton, Fla.--Clarence H. Ellis wants bids on both direct connected 45 kilowatt generator set and on 45 kilowatt belted generator, 60 hp. engine, and 75 hp. return tubular boiler, also on a 35 kilowatt generator set as above.

Shenandoah, Va.—D. S. Louderback, mayor, will receive bids until November 21 for furnishing this city with electric lights and motor power.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅝@16¾c.; Lake 16⅝@16⅝c.; casting, 16⅛@16⅜c.

The General Electric Company semi-officially announces that it does not contemplate the acquisition of any other electrical concern.

The Allis-Chalmers Company will soon remove its business from Chicago to its $3,000,000 plant now nearing completion at West Allis, Wis.

H. W. Parsons, cashier of the American Banking Company of Sandusky, O., has been appointed receiver of the Warren Electric Manufacturing Company of that city.

Stockholders of the Southern New England Telephone Company, at a recent meeting, voted to increase the company's capital stock from $5,000,000 to $10,000,000.

The Southern Traction Railway Company, which proposes to build a trolley line from Altoona to Roaring Springs, Pa., has made a mortgage to secure $500,000 six per cent. 10-year bonds.

The Brooklyn Rapid Transit Company's gross earnings for October have shown, it is reported, an increase of about $175,000 over October, 1904, and an increase of about $5,750 per day over last year.

The Chicago Edison Company has ordered two 8,000 kilowatt steam turbines and generators. These machines are each capable of developing 18,000 hp. This order is a duplication of one formerly from the same company for two similar machines.

General Electric was adversely affected by the announcement of a proposal to increase the amount of its capital stock. Wall Street argued that the value of the prospective rights was a relatively small consideration in comparison with the possible effect on the floating supply.

It is fully expected that the back dividend on United Railways Investment Company, of San Francisco, preferred stock will be paid the first of the year, in cash or some obligation worth par of the accumulated dividend, and that the preferred stock will be established on a full 5 per cent. basis.

The common stock of the Philadelphia Company crossed par Friday. For a month past experts representing Ladenburg, Thalmann & Co. of New York and foreign interests have been inspecting the property. It is understood that control is being bought. The company has an omnibus charter and controls the natural and artificial traction and lighting franchises of Pittsburg.

An important meeting of the directors of the Metropolitan Securities Company of New York was held Friday. While no action was taken, it is understood that the advisability of issuing a statement of the company's condition was discussed. It is not unlikely that such a statement may be issued after the next meeting of the board. There is no intention at this time of calling an additional subscription on Metropolitan Securities stock.

The termination of the written agreement between the Brooklyn Rapid Transit Company and its motormen will result in the increase of pay of some of the men. When the road was changed to electricity the old engineers were taken over as first-class motormen at $3 a day and the firemen were made second-class motormen at $2.50 a day. The second-class motormen will now be raised to the first-class. New applicants will be employed as second-class motormen for one year at $2.50 a day

EDITORIAL NOTES.

Risks Small, Profits Large.

An interesting book on telephone development has made its appearance. The author is Mr. F. S. Dickson, president of an Ohio telephone company. He states among other interesting things that a telephone company as an investment is wholly free from some of the commoner forms of risk. During times of general prosperity it reaps an advantage in the average inincrease in values, and suffers less, according to the author, when hard times come.

As it supplies a necessity of life its income is stable and the number of telephones may increase largely and steadily. It does not have to remove its exchange because of a change in the business center of a city. It is easy for it to extend its cables to supply increased demands. A large proportion of its property may be economically shifted to meet varying public needs, and new lines begin to earn money before the bills for labor and material are due. It does not make things to sell and therefore carries no large stock of goods, nor does it need to hold idle vast quantities of raw material. While the junk value of its plant is very high, there is little likelihood of its property ever being sold as junk. Its loss from friction need not be taken into account, from weather conditions is ordinarily slight, and from accidents infinitesimal. Properly maintained, its depreciation from natural causes is but little, and from the changing character of business far less than for a manufacturing or transportation company. It offers good rates for its bonds and promises with reasonable certainty handsome dividends on its stock.

Mr. Dickson is an authority on telephone matters, and it is fair to presume he knows what he is writing about. Such being the case and as the financial risks are so small in the telephone business, we should like to inquire why the public puts up with the exorbitant charges of the Bell companies?

The Puncturing of Insulation.

When insulation is punctured by means of a direct current it takes a pressure bearing some relation to the resistance of the insulation affected to break through the medium under stress. The manufacturers of high tension apparatus are particularly interested in the conditions which make insulation give way. The two expressions, insulation and dielectric, are synonymous in so far as the weakness betrayed by the insulation and the amount of inductive action are concerned. The degree of pressure developed ordinarily in power-carrying wires will not break through its protective covering as a rule. But extraordinary conditions prevail at times, with the result that it does give way, and in a most astonishing and apparently unexplainable manner. Perhaps the most familiar case to the general reader is that of lightning bursting through various forms of insulating materials, such as poles, windows, chimneys, trees, etc. A terrific potential like this, however, is that of inductive action due to it; a potential induced in neighboring bodies which, if sufficiently high, culminates in a disruptive discharge.

The ordinary puncture of insulation, by which is meant the breaking through of the covering of wire, is not caused by the normal pressure of the wire. It is due to conditions developing within the circuit, which give rise to a very high—an abnormal potential—for a series of intervals of time. The inductive action in this case is caused by electro-magnetic influences, primarily aroused by the self-induction within the circuit. It is best understood as a case of where the circuit, such as a transformer, for instance, develops within itself, when the self-induction and capacity are properly related, a condition of resonance.

Under these conditions the circuit can build up a very high electromotive force, sufficiently high with only a reasonably low pressure to break through the insulation. If the transformer takes one or two thousand volts, and the internal coil conditions permit the reactions spoken of to exist, then it is possible that a pressure of many thousands of volts will strain the insulation to its breaking point. What is meant here is that the electrical energy, under conditions which make the electrostatic capacity and self-induction balance, gives rise to a potential which threatens the integrity of the insulation. To present the facts even more clearly, it is as though certain influences were operating in a pipe carrying running water, which tended to fracture the walls of the pipe. While it is well known that by suddenly turning off running water an effect of shock is produced, called the water hammer, an effect which will burst weak pipes, the effect meant here is different only in so far as it is produced by an alternating flow of current. If the walls of a pipe are weak they can evidently be broken by an hydraulic impact, and in a similar manner if the insulation is weak it can be punctured by an electrical impact. While the two cases are not identical, they serve to illustrate the idea that in certain circuits carrying a comparatively low pressure alternating current a disruptive potential may be engendered that will cause severe damage unless understood and eradicated. Transformers represent such an instance, as shown at times by the complete breakdown of their insulation when in ordinary service.

* * *

An English Awakening. An important movement has been set on foot in Great Britain with a view to awakening among the masses of the English people an interest in, and belief in, the powers of science, such as have been long noticeable to a far greater extent among the people of the United States and of some European countries. The scientific spirit, it is complained, though so essential to all true progress, is still rare, and is too often lacking in an almost incredible degree in some of those who are responsible for the conduct of many of the British national activities. The movement to which we have referred, and whose object it is to remedy the evil and bring home to all classes the necessity of applying scientific treatment to affairs of all kinds, has now developed into what has been termed the British Science Guild. In this guild there being brought together a very large number of leading men interested in all different departments of science, including Lord Kelvin, Sir William Crookes, Prof. George Darwin, Sir Archibald Goikie, Sir Norman Lockyer, Professors Ayrton, Perry, S. P. Thompson, and so on; but it is by no means confined to scientists, for it includes representative leaders of all the great industrial and manufacturing organizations of that country, educational authorities, and indeed all branches of human endeavor whereon a beneficial effect would be felt from the wider applications of scientific method. The inaugural meeting of the guild was held in London under the presidency of the Lord Mayor on October 30, and many interesting speeches were delivered which excited the enthusiasm of a goodly gathering of sympathizers and gave the movement a good send off. To these speeches we need make no more than the briefest reference. Their purport was: If the English as a manufacturing nation wish to stand out prominently in the competitive struggle between the nations of the world, there must be an end to the apathetic treatment of scientific men and methods by Government departments; that the niggardliness of the Government in making grants to universities and other institutes where scientific education is imparted must end; that the "common people," if we may use a convenient though sometimes objectionable term, must be taught to think; and that the aptitude for scientific application shall be secured to the industrial worker in the factory as well as to the employer and the manager.

The latest bulletin from the so-called "electrical press bureau" is as follows: "The impression that J. P. Morgan and his friends hold a controlling interest in the General Electric Company is wrong. A majority of the stock is held by New England people. Westinghouse securities are very closely held by Pittsburg interests. Neither the Westinghouse nor the General Electric Company is endeavoring to secure control of the Allis-Chalmers or the American Locomotive Company."

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Clarence S. Darrow of Chicago, Mayor Dunne's expert in traction litigation, has resigned, "because he is disheartened that not one thing has been accomplished by municipal ownership followers."

The Japanese Minister to this country is making a thorough study of the manufacture of electrical machinery, and will report to his Government in December.

Prof. H. S. Carhart, of the University of Michigan, who recently went to Berlin, and participated in the conference on standards, etc., at the Reichsanstalt, is now visiting the Bureau of Standards at Washington, in connection with this work.

Manufacturers of gasoline motor trucks are up in arms because their vehicles are barred from many of the docks and piers in New York, while there is no objection to electric trucks.

The Brooklyn Rapid Transit Company is the largest street railway corporation in the world. It operates 538 miles of track and 3,600 cars, carrying on the average 2,000,000 passengers a day. The company has, within six months, spent several million dollars for additional electrical equipment.

A cable dispatch from Paris says the repeated complaints of the Parisians on the subject of the poor telephone service of Paris have at last spurred the Ministry of Posts and Telephones to institute reforms. The antiquated plant is to be replaced by a new one which will cost the Administrative Commission $10,000,000, and the general working of the system is to be operated on the American plan.

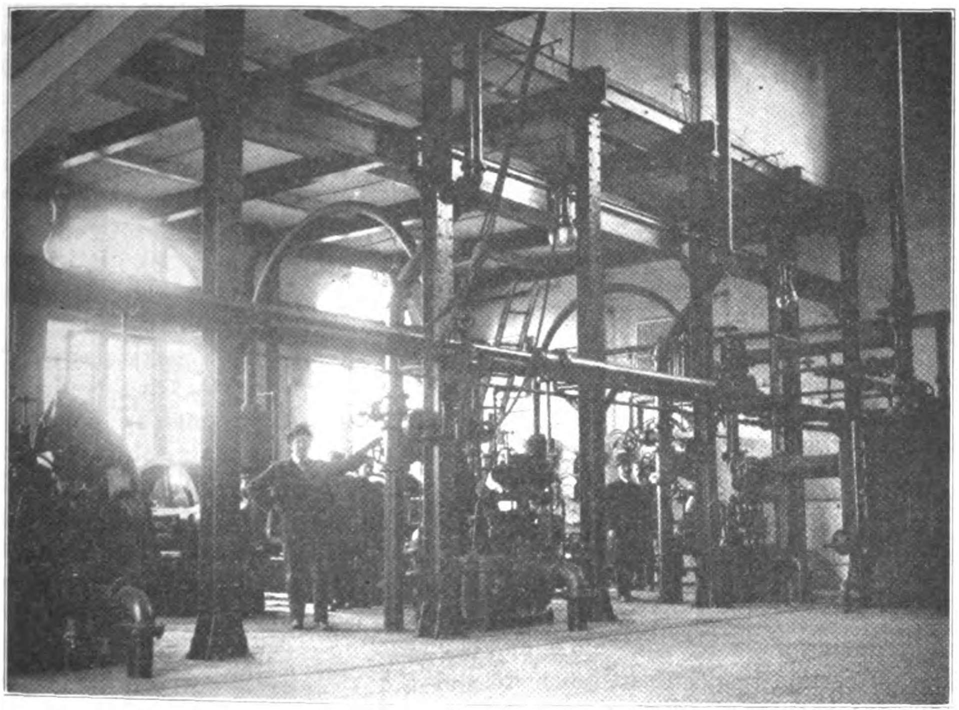
The Magnetic Club will hold its annual autumn meeting at the Hoffman House, New York, this (Wednesday) evening, November 15. Dinner will be served at 6:30 o'clock. Delegates to the annual meeting of the Telegraphers' Mutual Benefit Association, which will be held the same day, will be guests of the club.

Lieut. Ettore Rota, of the Italian Navy, has invented an apparatus for protecting crops from destruction by hail. One of the chief features of his invention is the use of the Hertzian waves. Lieut. Rota has carried out several successful experiments and has been warmly congratulated by the Italian Goverment.

AN EXPERIMENTAL MUNICIPAL LIGHTING PLANT IN NEW YORK.

BY IRVING THOMPSON.

European cities for some years past have been trying to extract the heat or fuel value from certain kinds of rubbish collected by the street cleaning departments. They have undertaken experiments and systematically employed means for advantageously disposing of that class of refuse which they believed would yield specific and profitable returns.

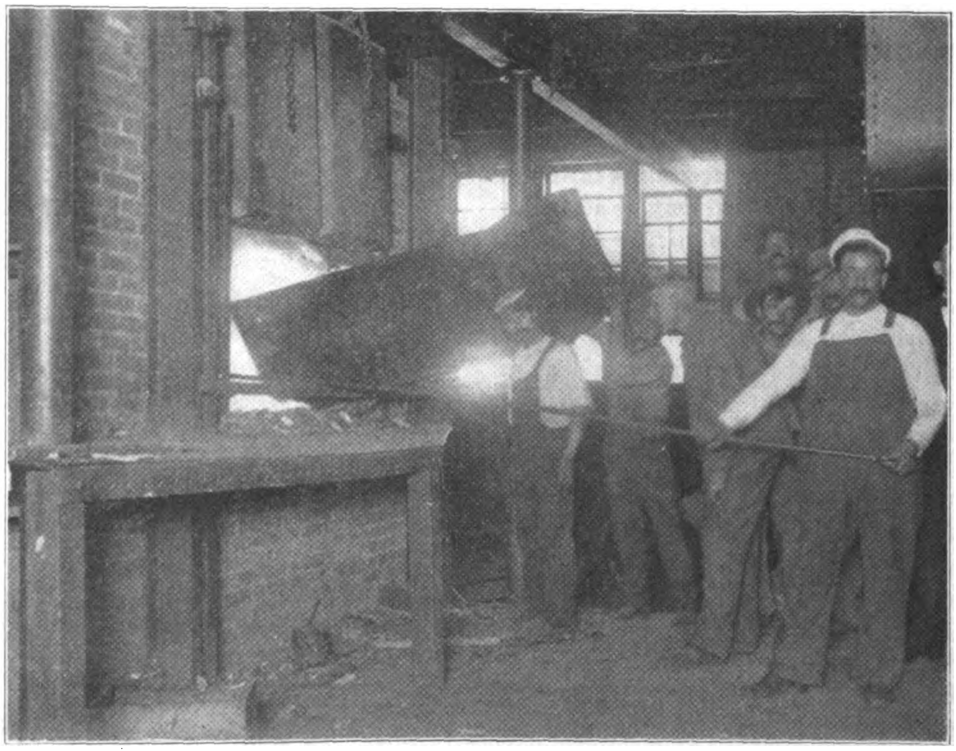


Generating Station of New York's Municipal Lighting Plant.

American cities on the other hand have paid no attention to this phase of rubbish removal, except in so far as they could have it removed quickly and completely from their sight. To facilitate this work they have been accustomed to paying large sums to contractors for its removal from the city streets. The reports proceeding from certain European cities have been the stimulating cause of an interest which crystallized in a determination to try a similar experiment in New York.

Two plants are now in operation based upon these theories, the second of which is described and illustrated in this article. Both plants make a point of consuming rubbish collected from the streets. This rubbish might be described as consisting of the following: Paper of all descriptions including cardboard; wood, including old furniture with its stuffing, barrels, boxes, etc. This material is burnt and its heat of combustion used to generate steam for operating an electric light plant, and supplying steam heat to public schools in the vicinity.

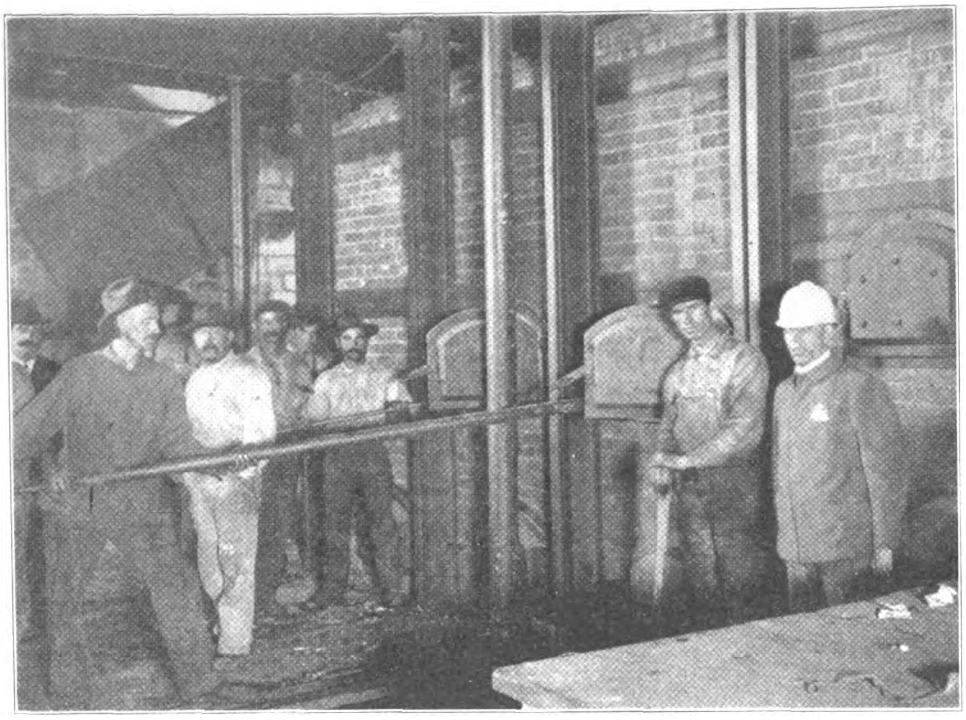
The plant illustrated was started up on October 30. It is situated directly under the new Williamsburg Bridge at Delancey street and the East River. The equipment is contained within two buildings, one housing the furnaces and boilers, the other providing accommodations for the generating plant. The first building covers an area approximately 150 feet by 70 feet and is 30 feet in height. In it the rubbish is received on the lower floor, and is dumped directly from the street wagons on to an endless conveyor, which carries it up an incline to a platform above the furnaces. This conveyor travels at the rate of 60 feet a minute, and as it carries the waste material upwards a gang of sorters pick out the material which in their experience would interfere with combustion. Several men and boys are stationed on either side of the conveyor, making the final sorting process a means of eliminating such unwieldy articles as would be likely to clog the chutes leading to the furnaces or limit the intensity of the active combustion.



Placing an Old Lounge in Furnace of New York's Municipal Lighting Plant.

When the matter reaches the top of this conveyor it falls on a sheet-iron platform containing openings which lead into three of the four furnaces. Through these three separate chutes the rubbish is pushed down by men with shovels. Owing to the draught caused by the chimney, built in connection with this plant, of a height of at least 80 feet, there is no possibility of the heat or flames coming up through these chutes and affecting the workers above. Back draught in this construction has been entirely eliminated, thus supplying an indispensable element of safety in conjunction with this class of work.

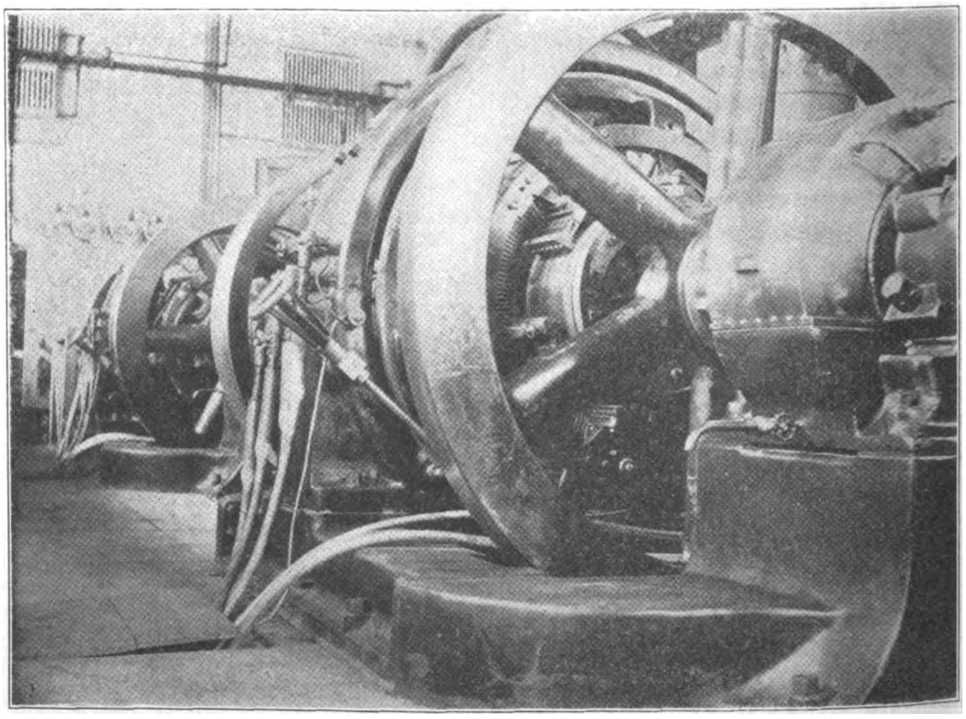
Along the outside of the building an inclined wagon way has been constructed, which is used only by the drivers whose wagons contain material requiring neither picking nor sorting. The fourth furnace is thus called into requisition, for it is utilized to consume the material from such wagons, which is dumped directly into a chute leading to it. By this means time and labor are saved which contribute directly to the financial advantages claimed by this scheme of disposing of waste material.



Firing Gang at Work in New York's Municipal Lighting Plant.

Such material as large pieces of lumber, entire barrels, old sofas and chairs, etc., which could not be dropped down through the chutes are thrown directly into the furnaces through the firing doors on the lower floor. The light and highly combustible nature of the material consumed in conjunction with the heavy draught caused by the chimney prevents any unusual waste of heat taking place when the furnace doors are opened as described.

A novel feature of the plant is the direct separation of the furnaces from the boilers. Advantages are derived from this arrangement, which may be stated as follows: First, the combustion is made complete so that the generation of smoke is practically impossible. Second, the use of the combustion chambers of the furnaces is thereby made independent of the use of the heat for making steam in the boilers. In other words, if the rubbish is to be burnt at a time when it is not deemed desirable to generate steam to do electric lighting, the plant merely represents a rubbish destructor. On the other hand, if steam is being generated, a series of short flues connecting furnaces and boilers, are opened by means of dampers, thus permitting the heat to play upon the boilers for the purpose intended, and at the same time supplying a means of consuming the smoke. This feature is of prime importance, because the bridge level and top of the chimney are in sufficient proximity to otherwise cause annoyance to passengers and pedestrians. Indirect connection, therefore, represents a means of overcoming a salient objection to the combustion of smoke-producing material, the smoke of which is in certain respects as much a fuel if properly utilized as the material itself.



Dynamo Room of New York's Municipal Lighting Plant.

It may be interesting to note in connection with this form of construction that the dampers, by means of which the flues are opened or closed, are made of fire-brick and not of iron. In this peculiar class of work, where smoke consumption, rubbish burning, steam generation and electric lighting are all carried on together, it is necessary to make provision for the preservation of each part of this equipment against the ravages of a variety of temperatures, when such part is exposed to the varying degrees of heat and flame. Dampers made of iron do not resist these influences sufficiently well, and it has been found necessary to substitute fire-brick in its place. Another reason is to protect the boilers from the heat of combustion when they are temporarily out of commission.

Two Sterling boilers are employed which have a rated capacity of 200 hp. apiece. They are built in and supported in the usual manner by a brick foundation. The present capacity of the plant is 160 loads of rubbish a day, each load weighing 1,000 pounds. The handling of this material in this particular department of the plant calls for the efforts of 25 employes. These men are engaged to pick and sort the material, to fire the boilers, and to oversee the work. The peculiar situation presented here is that of the Department of Street Cleaning superintending the handling and combustion of the rubbish, in fact, this particular building is entirely in its charge, and the responsibility for its proper supervision rests upon its shoulders. On the other hand the lighting plant, which is, as stated, installed in a separate building, is directly under the management of the Department of Bridges.

Previous to the installation of this plant the city of New York was spending 30 cents a cubic yard to dispose of its waste products; calculations based upon the operation of the present plant have not as yet been made with sufficient accuracy to present reliable statistics on the subject. Part of the residue of combustion from the furnaces has been turned to profit by being packed and shipped to tobacco growers, who find this quality of ash of particular service to them in that industry. In addition, much of it is placed on scows and used in various sections of the water front for filling.

The electric plant utilizes the steam at night for lighting the Williamsburg Bridge, and during the winter season the public schools in the immediate neighborhood are supplied with steam heat. It has been estimated by Mr. F. L. Stearns, the engineer of the Department of Street Cleaning, who designed and built the rubbish-consuming plant, that one pound of the material burnt in the furnaces is capable of evaporating one and a half pounds of water from 212 degs. Fahrenheit. This means that condensed steam returned to the boilers can be, like any other plant, economically utilized. If the water is below 212 degs. Fahrenheit, it is evident that more than one pound of rubbish will be required to evaporate one and a half pounds of water. On this basis a calculation made, resting upon the belief that 24 pounds of steam are necessary to produce one horse power hour, the division of 24 by 1.5, giving 8, would show that 8 pounds of rubbish are necessary to develop an equivalent amount of power. A calculation of this character would tend to show that every wagon load of 1,000 pounds of rubbish dumped into the furnaces would develop 125 hp. hours. An estimate of the number of horse power hours required in the form of electrical energy to do the lighting of the bridge would be a means of calculating the number of wagon loads of rubbish necessary to provide an adequate supply of heat energy. On the basis established, derived from the figures given, about fourteen 16 cp. incandescents, or two inclosed arcs, could be lit one hour from the heat obtained by the combustion of eight pounds of rubbish. Both the labor bill and the rate of depreciation must be included in any calculations giving rise to practical data on the subject.

The electric generating plant is necessarily merely the recipient of this mechanical energy developed through the boilers and engines. It is situated in a building 60 x 30 feet in area, adjacent to the rubbish-consuming plant, on the lower floor of which is installed the generators and engines. There is an upper floor covering about one-fourth of the area of the building, which will be used as a storage battery room when equipped. This last system will be a sort of buffer between the fluctuating steam pressure and the electric lighting. It will also serve to take care of the load where an excess of energy is developed. At present there are three generating units consisting of cross compound Ideal engines direct-connected to Burke generators. Two of these engine units are of 100 hp., and one is of 75 hp. capacity. The three-wire system is employed throughout; the potential across the positive and negative leads being 240 volts.

In connection with the steam plant it may be stated, in conclusion, that the steam after passing through the cylinders is sent into Cochrane oil separators and into condensers. The customary and economic measures in all modern steam and electric plants are put into service to gain as high an efficiency as possible when and after the steam is used. Artesian wells have been sunk to gain a water supply for boilers and circulation around the condensers, and in addition to avoid an expense which would otherwise exist for condensing purposes.

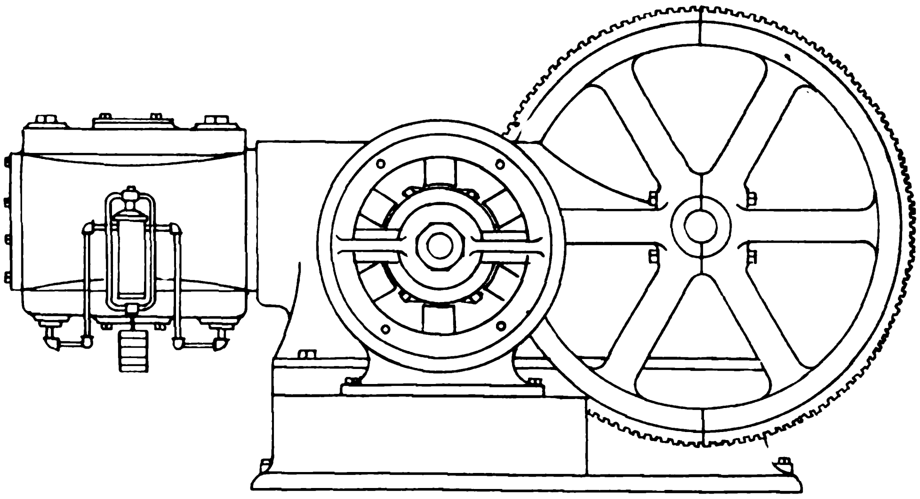


FIG. 1.

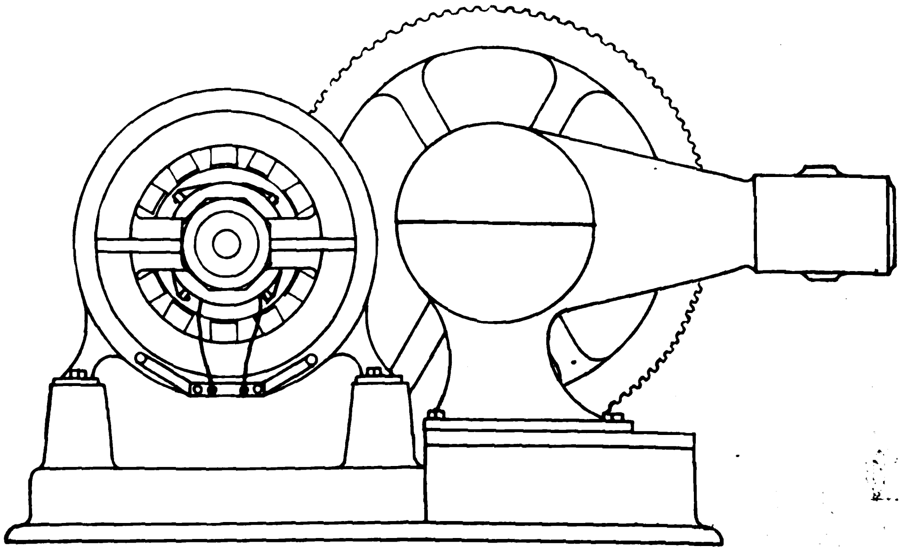

FIG. 2.

The buildings are fireproof throughout with cement floors and steel girder construction. Engines and dynamos are mounted on the same bed-plate, as illustrated. The switchboard consists of eight panels arranged as follows: Four feeder panels, one meter panel and three generator panels; the necessary circuit breakers, non-arcing fuses, switches, etc., including lightning arresters, are supplied to equip this center of distribution.

MOTORS IN BOILER SHOPS.

BY W. H. WAKEMAN.

A steam engine of some kind or description is usually found in every boiler shop, as power is required for various purposes. Some of these shops are driven by first-class engines that are cared for by competent engineers; while others have to get along with fourth rate machinery.

Compressed air is used for various purposes, such as driving rivets, chippers, caulkers, etc., thus displacing a vast amount of hand labor. Steam-driven compressors are sometimes located in these engine rooms, where they prove to be objectionable on account of the noise they make and the vibration they cause.

Not far from where I am writing this article, there is a fine boiler shop driven by a good Corliss engine in charge of a very competent engineer. The engine room would be quite a comfortable place, were it not for a large steam-driven compressor, which makes so much noise that communication must be carried on by shouting, as ordinary conversation cannot be heard. This is not only an annoying condition of affairs, but it prevents the engineer from hearing noises which indicates that some part of his engine or pumps needs attention, by which warning he is often enabled to avoid serious trouble. It must be a serious defect indeed that would cause noise enough to be heard in that engine room, yet somebody must spend many hours per week amid its discomforts.

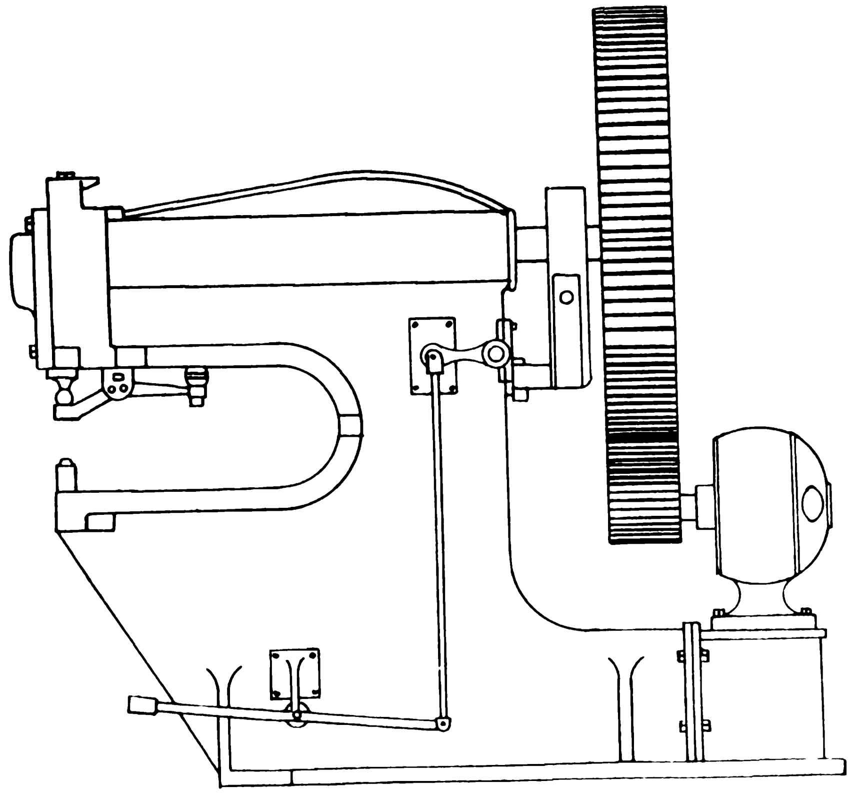

Fig. 3.

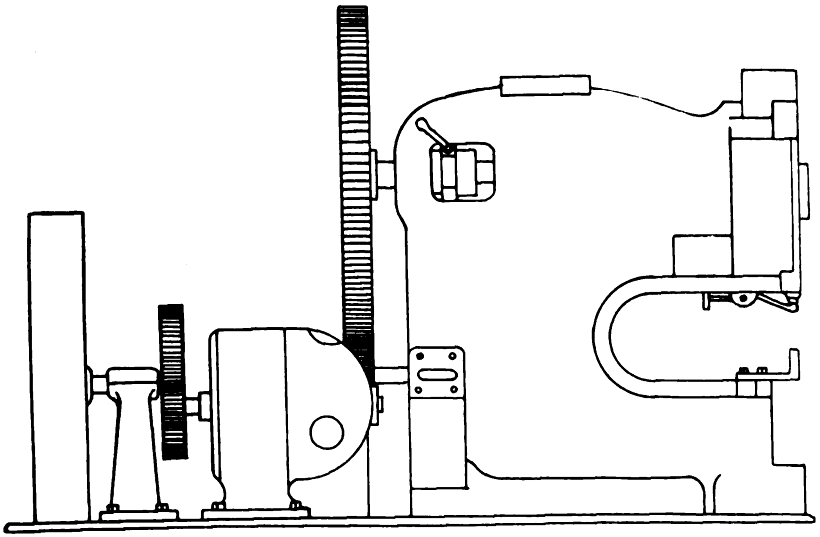

Fig. 4.

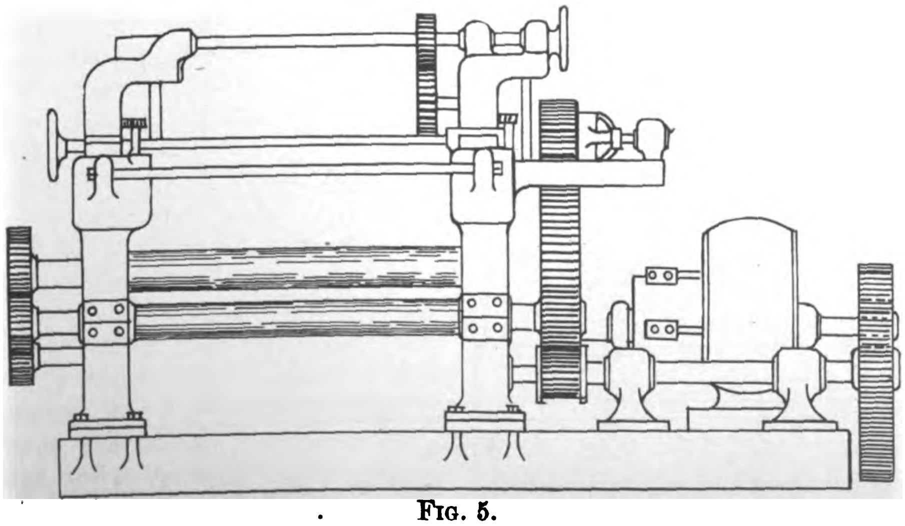

Fig. 5.

How much better it would be to locate a quiet running generator in that engine room, transmit power to a motor driven compressor, like Fig. 1 or Fig. 2, located right in the room where compressed air is wanted. A boiler shop in operation is always a noisy place, therefore the extra noise caused by this machine could do no harm. I have not heard of a case where this experiment has been tried and abandoned.

Punches are used in modern boiler shops and as a rule these can be driven by motors to good advantage. Fig. 3 illustrates one of these on which a large gear wheel revolving slowly, acts as a balance wheel with good effect. It will be noted that this balance wheel is directly on the main shaft of the machine, therefore when the punch strikes the metal to be worked, the momentum of this wheel carries it along without strain on the motor, or any other part of the mechanism except the main shaft

I have seen a belt-driven punch on which the belt was very slack, punch out an elliptical-shaped hand hole about 4 x 5 inches without tightening the belt, as the fly wheel did the whole of it.

Fig. 4 is another motor driven punch, but the design is quite different. There is a spurgear on the armature shaft at the left, which meshes into a larger gear on an independent shaft which also carries a fly-wheel on one end outside of the bearing, and a spur gear on the other which meshes into the large gear on the main shaft.

The effect of this in practice is to run the fly wheel at a high rate of speed, while the largest gear runs much slower, and as it is comparatively light, it gathers but little momentum. The strain of suddenly operating the punch is transmitted from the fly-wheel through the independent or auxiliary shaft, by means of two gears, but no strain is brought upon the armature shaft.

This line of argument and presentation of facts does not mean that the writer is an advocate of the idea that a fly wheel adds power to a machine, because it does not. Of course it gives out power when wanted in this and similar cases, but all that it furnishes (and more too) was put into it by the motor or engine that drives it, as the case may be, consequently it absorbs power that can never be reclaimed. We use such devices as a matter of convenience, and are contented to put more power into them than we take out, because it enables us to work to better advantage, making it a paying investment.

Fig. 5 is a set of boiler plate rolls driven by a motor. As these rolls always turn slowly but require considerable power at times, the motor travels at a high speed which is reduced first by heavy sprocket wheels and a silent chain at the right hand side, then by suitable gears shown between motor and rolls.

This certainly is in great contrast to the old-fashioned rolls turned by inserting long hand spikes in them, relics of which may still be seen around some of our old boiler shops. It is also superior to other means of driving rolls of this kind on account of the ease with which a plate may be handled, also because the apparatus may be located anywhere it is wanted without regard to location of shafting.

Small portable electric motors are used in boiler shops, competing with pneumatic tools, proving both convenient and economical.

After a man has used a petticoat lamp burning lard oil inside of a boiler until the air becomes saturated with smoke and vile odors, he appreciates a clean electric lamp and does better work accordingly.

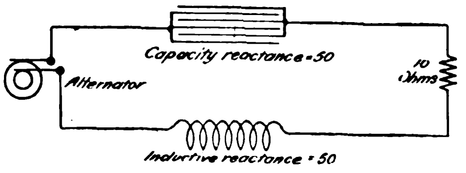
LIGHT, HEAT AND POWER PRINCIPLES.—VIII.

BY NEWTON HARRISON, E. E.

Resonance in Circuits.—By resonance in circuits is meant a condition in virtue of which neither the capacity or inductive reactance is individually operative. While both are present, yet neither appears except as a cause for a high internal electromotive force. The circuit in which both these influences exist then acts as though there were only resistance present. The condition is expressed by the statement that the impedance due to inductive and capacity reactance is zero. For instance, if the resistance of a circuit carrying an alternating current were 10 ohms, and the capacity and inductive reactance equal respectively to 50 apiece, then, according to the formula, the impedance equals the square root of $10^2 + (50 - 50)^2$ which equals 10. In this case the formula for impedance has been closely followed and values given to the indicated symbols. The formula is expressed as follows: Impedance =

$$\sqrt{R^2 + \left(p\ L - \frac{1}{pK}\right)^2}$$

in which R = ohms, $p = 2\pi f$ where f = frequency, L = inductance and K = capacity in farads. The fact that in the example given, p L was made equal to $1 \div p\ K$, means that the inductive and capacity resistance when made equal create a condition within the circuit the same as though only ohmic resistance were present. For this reason a circuit is in a resonant condition when the obliteration of each particular effect is complete enough to leave only room for the purely ohmic effect. When a circuit has a resistance of 10 ohms, and an inductive and capacity reactance respectively of 50 ohms equivalent, then the



Circuit in which capacity and inductive reactance are equal, making it resonant. Only resistance remains.

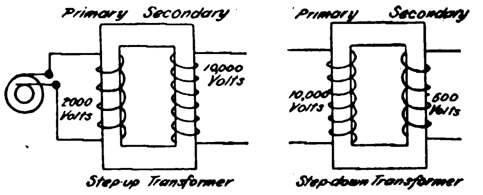
$$\sqrt{10^2 + (50-50)^2}$$

is evidently equal to only 10. But although only a 10 ohm resistance actually remains, the inductance within the coil is capable of developing a very high electromotive force. If, for instance, 100 volts are applied, then $100 \div 10 = 10$ amperes in the coil; but the reactance due to self-induction is 50, therefore the EMF. of inductance will equal $10 \times 50 = 500$ volts.

This represents the degree of reaction due to the inductance or inductive reactance multiplied by the current. The presentation of these facts is made for the purpose of showing how power and lighting circuits are affected by inductive and capacity reactances. To recapitulate, lead is caused by capacity operating in a circuit to a great enough extent to hurry the current forward; lag is caused by inductance operating in a circuit to a great enough extent to retard the progress of the current.

The technical form of expression given is that the capacity causes the current to lead the impressed EMF.; also that self-induction causes the current to lag behind the impressed EMF. The effect of the resistance itself is to cause both the current and EMF. to be in perfect phase with each other. In other words, if an electric circuit was not affected by capacity or inductance, if neither were present, the current would not lead or lag, but be in phase with the impressed EMF.

The Transformer.—Alternating currents are successfully handled in connection with electric light and power work by means of transformers or converters. There are two general classifications to be made of this particular form of apparatus. First, the ordinary type of transformer, by means of which an alternating current of high potential can be converted into one of low potential, or *vice versa*. Second, the class of machines, termed rotary converters, by means of which an alternating current can be transformed into a direct current, or *vice versa*. By means of both types of devices, alternating and direct current can be moulded to suit the wishes of the engineering experts intrusted with the design and development of any such propositions. It is needless to add that both the transformer and the rotary converter are closely associated together in the work of transmitting and distributing electricity for light and power purposes. The method of combining them is shown in the illustration, which shows how an alternating current is handled from the source of its generation to the point or points of distribution. The various processes involved may be noted in the following synopsis:



Transformers for raising and lowering voltage.

First—The hydraulic or mechanical energy obtained from water power or the burning of coal, oil or wood is utilized to produce rotation.

Second—The electrical generators are connected up for the purpose of transforming the mechanical energy of rotation into two or three phase alternating of a pressure varying from 500 to 2,000 volts or over, as the case may be.

Third—The alternating current thus generated is sent into one or more step-up transformers, whose function it is to raise the potential, without any considerable loss of energy, to an economic value for efficient transmission.

Fourth—The high tension alternating of from 5,000 to 6,000 volts is transmitted over the power lines to a point at which the first step toward distribution takes place in lowering the potential.

Fifth—The station or stations receiving the high tension alternating current convert it in one or more step-down transformers to a lower pressure while retaining a reasonably high efficiency in the process.

Sixth—The electricity is then transmitted to one or more rotary converters, which transform the alternating into a direct current ready for distribution. The low pressure alternating can be distributed at once for power and light purposes, but it is the usual practice, where trolley systems are to be operated, to convert the alternating into 500 or 600 volts direct. The forms of energy involved in this complicated process are as follows: First, medium pressure alternating; second, high pressure alternating; third, low pressure alternating; fourth, low pressure direct current. As each of these transformations involve the use of a device, whose efficient operation determines the power returned from the process, it is evident that the character of the process itself must be ultimately examined to grasp the limitations of the efficiency involved.

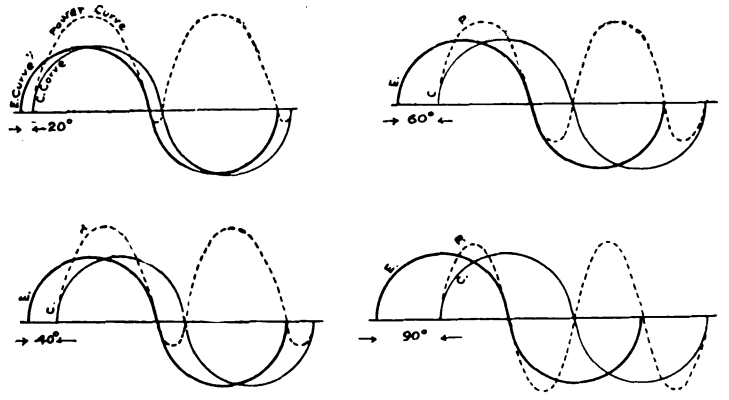
Rotary Converters.

Single Phase Current Power.—The amount of power produced by a single phase current is best known by reference to the power factor. The greater or less this is the greater or less the single phase power in the circuit. The plotting of the EMF. and current as two sine waves, with the difference of phase showing between them, does not convey in an adequate manner the amount of power involved. Calculations taking into consideration the power factor will do so, as, for instance, if the power factor is 80, 90 or 95, and the volts 100 and the amperes 10 or a product of 1,000, then with these power factors the total power in each case would be 800, 900 and 950 watts respectively. But this condition can be represented by means of a curve, showing the conjunctive action of the EMF. and current in each and every case of this character arising.

Power Curves.—What are called power curves are simply illustrations of the principle, simple in itself, of multiplying together the volts and amperes of power to obtain a new curve embodying this product. The sine wave of the volts consists of a curve due to a variety of values of EMF. Each point on the curve is represented by a vertical line called the ordinate. The termination of this line is the point of the curve, and an immense number of values between one zero and another gives the curve itself. The volts are therefore an instance of a rise of EMF. from zero to a maximum called the amplitude, and a comparatively gradual drop to zero again. The same is true of the curve of the current. It has its two zero values where it begins and ends, and its amplitude as well. If the two ordinates at any given point, or at all points of the curves, are multiplied together, it is evident that where only one ordinate is found, and the other is missing, there is no power. The same is true where the zero points are found on both curves. The fact must also be considered that the power curve thus drawn will be partly above and partly below the locus or zero line. The only exception will be found when there is no difference of phase between the EMF. and current.

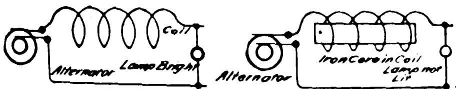


Power curves more below the zero line as the angle of lag increases, until at 90 degs. curves above and below are equal.

This condition will be considered in connection with those cases arising where the phase difference exists. Examination of the curves of EMF. and current, showing a lag of the current behind the EMF., indicates a series of zero values for both the EMF. and current. The first zero value is found where the EMF. begins. The second zero value is found where the current curve begins. The third zero value is found where the EMF. curve ends preparatory to the beginning of a new curve on the under side of the zero line. The fourth zero is found where the current curve crosses the zero line after becoming zero, and about to begin a new curve on the under side of the zero line. The fifth zero is found where the EMF. curve on the under side of the zero line returns to the zero line, and to zero. The sixth zero is found where the current curve on the underside of the zero line returns again to the zero line and to zero. The six zero points will always appear when there is a lag between the EMF. and current. They are significant because they represent the six zero points of the power curve constructed by multiplying the EMF. and current ordinates together. Wherever a zero point appears it is evident there can be no power, however large the ordinates of the other element of power. For this reason the curve of power will rise above the zero line where there are only positive ordinates to be multiplied together, and it will fall below the zero line wherever there are positive and negative ordinates to be multiplied together. But it must be remembered, that it will also rise above the zero line whenever *negative* elements are multiplied by *negative* elements. The zero line, it may be known, with reference to this state of affairs, indicates also the difference between the power consumed and the power returned. For instance, the extent to which the power line dips below the zero line, is a measure of the amount of negative power or power returned to the generators. The extent to which the power line appears above the zero line, is a measure of the amount of positive or available power that is or can be utilized. When the ordinates of the EMF. and current are therefore multiplied together, the power curve will be found to rise above the zero line and fall below it, rise above the zero line and fall below it, forming a curve of four amplitudes when lag exists. As the lag increases or diminishes, the power curve appears more below the line or above it. With great lag it is more below the line. With less lag it is more above the line. When the lag equals 90 degs., it is as much above the line as below it. In other words, there is as much power returned to the generator as it sends out. Illustration of these cases are given for the purpose of showing the ebb and flow of the energy, both when such ebb and flow is useful and when it is useless.

When the Power Factor is Zero.—When the power factor is zero, it means that the angle of lag equals 90 degs. between the current and EMF. In this case, the cosine of this angle equals zero, and the multiplication of the current and EMF. elements, however large, when again multiplied by the power factor zero would give only zero. But this does not mean an absence of electrical energy in the circuit; its elements are there but not in an available form. Therefore the false power pulsates in and out of the circuit without accomplishing anything. The fact that the power wave is equal above and below the line clearly indicates this pumping out and withdrawal of the electrical energy from the generator into the circuit and back again. An alternator producing a current with a 90 deg. lag is therefore only consuming enough energy to run as an idle machine. Friction and certain iron losses are the only ones met with. To make it consume more power it must establish a current in a circuit in which the lag is less than 90 degs.

Examples of Lag.—Practical examples of lag may be given and illustrated, to show the ideas contained in this exposition of its meaning with respect to the total power. One or more incandescent lamps may be connected in multiple, with a coil inserted in one leg of the line. The current is alternating, and the coil of such a low resistance, that the candle power of the lamp is not affected. The coil must be so wound that it will receive a core of divided iron of a high quality. The following series of experiments may then be tried: First, the lamp and coil in series will cause no change in the candle power of the lamp. Second, a core of iron inserted a very short distance within the coil will cause a perceptible lowering of the candle power of the lamp. Third, the insertion of the core about one-third or one-half the distance, will cause the lamp to drop in candle power to a bright red. Fourth, the total insertion of the core will serve to put the lamp practically out. The explanation given is two-fold and as follows: The coil in the first place has very little inductance reactance, because the effects of self-inductance are not very marked. The permeability μ is only equal to 1, and the inductance in consequence limited. But with the introduction of an iron core the number of lines of force increase, the self-induction increases, and the lag and impedance also increase. This is made manifest by the drop in candle power to a point where no light appears, because the energy has been almost entirely choked. This idea is of great value in forming a proper estimate of the reactions occurring in the primary and secondary coils of a transformer.



Effect of inductance of the light of a lamp.

The regulation effected by which a uniform candle power is preserved in the lighting circuits, depends upon the crystallization of such principles.

TURBINES VS. RECIPROCATING ENGINES.*

BY DECAPOD.

As turbines are now becoming close running rivals with reciprocating engines for different classes of work, chiefly electric generator driving and ship propulsion, a valuable criticism on the operation of the two methods of obtaining the most efficient and reliable prime mover may be raised.

In the case of the reciprocating engine, its operation is so well known that little can be said to enable it to be understood better than it is at present; it has almost reached the peak of its efficiency and reliability of operation for long runs under the worst conditions, such as driving a generator for heavy railway traction or shipwork in a heavy sea. Limits of steam pressure and temperature are low—450 degs. F. for steam temperature is as high as can be considered safe for keeping good smooth rubbing surfaces, such as valves, pistons and rods; higher temperatures necessitating expensive lubricating oils and a certain amount of uneasiness on the part of the man in charge if the engine is running with fine clearances. Then if surface condensers are used, there is always the trouble of extracting the oil from the hot-well before water can be used again for boiler feed. With triple-expansion engines it has been proved that a 26 inch vacuum gives the best results, and further, there is a limit to the expansion carried out in the low-pressure cylinder, due to the condensation and re-evaporation of steam on the cylinder walls, etc. The advantages of reciprocating engines over turbines for shipwork is in the manœuvring, the small size of propellers necessary for the high speed of turbines making it more difficult, especially from rest in narrow waters.

Trials have been made which show that turbine steamers going full speed ahead can be brought to rest in about a minute and a half. This is a good result, but actual experience has shown the relative inadequacy of going astern from rest. The case of the turbine is a most favorable one especially for central stations, it being an ideal drive for alternating-current generators in parallel on account of its equal turning movement. The turbine being a purely rotary motion with no rubbing surfaces, high pressure and temperature steam can be used with its full advantages, the only thing being slightly increased peripheral blade clearances for extra high superheat. The steam consumption of a turbine can be improved by 10 per cent. for 100 degs. F. of superheat with steam at 160 lbs. square inch. Then, again, it pays to have the best vacuum possible, and the steam can be expanded to its utmost limit. The gain from an increased vacuum is so great that it is advisable to pay great attention to the design and upkeep of the condensing plant. For shipwork it is sometimes usual to fit a vacuum augmenter, by which means it is possible to maintain a vacuum of 28½ inches in the condenser. Another good feature of the turbine is that it requires no lubricant mixed with the steam, therefore obviating the necessity of any oil extraction from hot-well water. In large turbines for central stations it is usual to have the bearings lubricated by the oil gravity system—that is, with a tank some 40 feet above the engine-room floor level, into which the oil is pumped from another tank below the engine-room floor level, the oil running from top tank through the bearing and into the lower tank to be filtered and cooled, then pumped up to the top tank to be used over again. Oil treated in this way will last for months, care being taken to keep water out of the oil, as it sometimes leaks through from the water-jacket on large bearings, on account of leaky castings.

As in all engines, the governor is a very important consideration; a fly-ball type of governor is made use of. The speed of the turbine can be varied within all the limits of the governor spring whilst the turbine is running. This is particularly useful for bringing alternators into synchronism and adjusting their differences of load when in multiple. There being no variation of angular velocity in the turbine, which is necessarily present in reciprocating engines, heavy synchronizing currents between two alternators in parallel are avoided. All power being transmitted rotatively, foundations are cheaper than for the same output in reciprocating engines.

---

*From the "Electrical Engineer," London.

Many people imagine that the blades wear under the action of steam, but experience shows that with superheated steam this is not so. In the case of where steam is admitted through nozzles, slight wear is noticeable in the nozzles, owing to the tremendous velocity of the steam. If there is any water in the steam, this wear is increased tenfold. The bearings of a turbine require to be run with very fine clearances, .008 inch being usual with forced lubrication. Very fine centering of the spindle in cylinder is necessary, as the peripheral blade clearances in sizes up to 500 hp. are usually only .02 inch with 100 degs. F. superheat; with sizes of 7,000 hp., with the same superheat, .08 inch clearances are necessary. The spindle should always be in perfect running balance on account of the fine peripheral blade clearances.

The usual method of balancing heavy spindles is to lay them on knife-edges, gravity causing the heavy parts to come to the bottom. This method usually suffices, but no degree of real accuracy can be attained, as one cannot tell for certain which end requires the additional weight to bring it into balance. With smaller sizes it can be run up to speed and marked with a colored pencil at different points, which shows where to add additional weight. A small body revolving at 5,000 r.p.m., the light side is always the one that comes out, so that weight should be added where the marks are. In some cases the marks are different at each end, when weight needs to be added at each end to suit.

For slower speeds than 5,000 r.p.m. the marks usually come at certain angles, leading the light side this can easily be found by trials. As there are so few moving parts in a turbine compared to the numerous moving parts in a reciprocating engine, the repairs and replacements are small in comparison.

Greater economy in oil and attention is on the side of the turbine, as they run cleaner, and all that has to be done is to turn on the steam and keep an eye on the oil to bearings. The chances of breakdowns on both the reciprocator and the turbine are probably equal, and the most serious break down for a turbine is the wearing down of the balance pistons through allowing them to come in contact with the cylinder casing. As the rings of these pistons are solid with the main spindle, it means turning off the whole of the piston and shrinking on a new one. This is a long job, and means throwing the turbine out of service for at least four weeks. Another serious breakdown is likely to happen from loss of oil to bearings. Such accidents have happened, causing bearings to seize and put such a strain on the spindle as to bend it. Once bent it is difficult to get it back to its original position and seldom to make it run as true as before accident. A strip in the blades is for shore work usually a stoppage of about five days in small sizes, and repairs can be effected on sight with ease, the reblading not being as difficult as it would appear to be.

With good tools and men used to the work, it is surprising how soon a few thousand blades can be fixed in position. There is usually no sign indicated previous to a strip, and the first thing noticeable is a sudden grinding, then a full stop, the blades shearing off close to the main body of the spindle and becoming wedged between the spindle and the cylinder casing, no damage being done to any other part beyond the actual blades. The usual cause of strips may be put down to too fine clearances with excessive superheat, spindle being out of balance, and shaft whipping causing blades to rub, a heavy dose of water from boilers while on load, or a weak blade breaking off and fouling. A strip does not mean the whole of the blades, and may be anything from two rows to twenty. These three breakdowns are the only ones that can happen of any serious moment, and with the ordinary amount of care and intelligence it can be proved that the turbine is becoming as reliable as the best reciprocating engine.

* * *

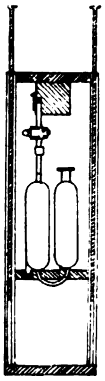
WRINKLES.*

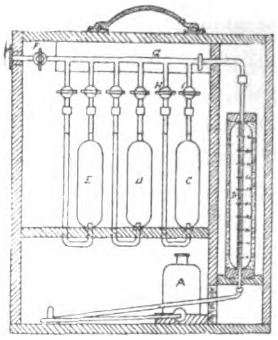
EDITED BY H. C. ABELL.

An Apparatus for the Rapid Analysis of Flue Gases.

The analysis of flue gases as ordinarily conducted with the D'Orsat or Hempel apparatus requires considerable time, if accurate results are to be obtained, so the apparatus presented here was designed to enable analyses to be made more quickly. The essential feature is the introduction of the gas in the re-agents in a finely divided stream at the bottom of the absorption pipettes, so that it bubbles through the liquid and consequently comes immediately into intimate contact with it.

A is the leveling bulb; B is the measuring tube which is water-jacketed; C is the first absorption pipette, in which caustic potash is used to absorb carbon dioxide; D is the second absorption pipette, in which potassium pyrogallate is used to absorb oxygen, and E is the third pipette, in which cuprous chloride is used to absorb carbon monoxide; F is the inlet cock; G is the header; H is the inlet cock to one of the absorption pipettes, and I is the outlet cock to one of the absorption pipettes.





The method of analysis is as follows: A sample of gas is drawn in through the cock F, along the header G to the measuring tube B by lowering the leveling tube A. A little more than 100 cubic centimeters are taken in. The leveling tube A is then raised so that the water in it is even with the zero mark on the measuring tube B, and the cock F is open for an instant, so that the gas in the tube B comes to atmospheric pressure. The cock F is then closed, and the tube B contains 100 cubic centimeters of gas at atmospheric pressure. Cock I is then opened, and the bulb A is slightly raised, so that about three cubic centimeters of gas is transferred to the pipette C. This is done to clear the capillary tube at the top of C of the re-agent, The cock I is then closed and the cock H is opened and the rest of the gas bubbled in through it at the bottom of the pipette. When the gas is all in the re-agent is drawn back into the capillary leading from the bottom of C to H, and the cock H is closed. The cock I is now opened, and the gas is drawn back through it into B by lowering A. The cock I is then closed and the gas in B measured in the usual way. This operation is repeated in the pipette C until there is no further absorption. The gas is then transferred to D and E and the same process repeated.

If care is taken at the close of each analysis to see that the cocks are greased with vaseline, there will be no trouble from the tendency to stick, which has been frequently advanced against the use of glass cocks in gas-analysis apparatus.

---

*Paper presented before the National Electric Light Association at its 28th convention. held at Denver-Colorado Springs, Col., June 6-11 1905.

W. B. TUTTLE, Long Branch, N. J.

Canvassing Gas and Electric Light Companies.

A report from Albany, N. Y., Monday, says the Commission of Gas and Electricity is engaged in making a canvass of the gas and electric light and power companies of New York State and each company, municipality and individual engaged in the business of furnishing gas or electricity for lighting or power purposes is asked to give certain details of stock and bond issues, amount invested in the plant and capacity and price charged for public and private lighting and power purposes. About 150 reports have been received, including reports of the New York City Edison Company and all the Brooklyn companies.

Jersey City-Newark Tunnel to be Built.

An underground railway, 8½ miles long, and tunneling the Passaic River, is to be constructed from Jersey City to Newark, in place of a mile and a-half spur of the Hudson & Manhattan Railway, to have been built in Jersey City. A certificate abandoning the proposed spur, and setting forth the intention of constructing the underground road has been filed with New Jersey's Secretary of State, and $16,800 deposited as an evidence of good faith.

The proposed branch will start in Jersey City on the Pennsylvania Railroad property, pass through Kearney and Harrison, and after entering Newark, will follow that part of Railroad avenue south of the viaduct of the Pennsylvania Railroad.

From Steam to Electricity.

The Pennsylvania Railroad Company has decided to go ahead with the plan to equip with electric power the old West Jersey & Seashore Railroad to Atlantic City, and some of the suburban lines out of Camden.

This was announced Monday in Philadelphia by Samuel Rea, third vice-president of the company, and chairman of the special committee having the matter in charge. He said it would take a year to complete the work.

N. E. L. A. Proceedings.

It is expected that the book of "Proceedings" of the 28th convention of the National Electric Light Association, held at Denver and Colorado Springs, will be ready for distribution about November 20. The papers, reports and discussions presented at the conventions of this association are now so voluminous, they can no longer be bound in one volume, and, following last year's precedent, this book will be issued in two volumes, Vol. II containing the Question Box and Wrinkles, which alone comprise over 700 pages.

Chicago's Electrical Show.

Chicago is fast getting everything into shape for its first annual electrical show, which is to be held at the Coliseum from January 15 to January 26. Thomas R. Mercein is general manager, with offices in the Monadnock Building. In the Coliseum there are 38,000 square feet available for exposition purposes.

Lectures at the University of Minnesota.

Mr. E. P. Burch, consulting electrical engineer, is giving a course of lectures on "Heavy Electrical Railroad Work," at the University of Minnesota. The subjects of the individual lectures are "The Physical and Financial Advantages of Electric Traction for Heavy Railway Work," "The Speed-Torque Characteristics of Steam Locomotives," "The Speed-Torque Characteristics of "Electric Locomotives," and the "The Physical Data for the Electrical Equipment for Operating a Division of a Trans-Continental Railway."

These lectures are based upon the investigations made by Mr. Burch for some of the Western railway companies, which are investigating the feasibility and desirability of electric traction upon certain divisions on their main lines.

Subscription Agents Wanted.

There is a splendid offer made to agents by "The Four-Track News," one of the most popular magazines in the country and one of the very best sellers. Subscription agents are wanted everywhere and large profits are assured. It will pay you to write to George H. Daniels, publisher, 7 East 42d street, New York, for full particulars.

Mr. Robert McF. Doble, consulting engineer of San Francisco, Cal., has severed his connection with the Abner Doble Company in order to resume his individual practice.

ELECTRICAL PATENT RECORD

LETTERS PATENT ISSUED NOV 7, 1905.

Electric Railways and Appliances.

803,793. Insulated Rail-Joint. Reuben W. Smith, Bryn Mawr, Pa. Filed May 26, 1905.

803,806. Trolley-Wheel. Emile Brossy, West Hoboken, N. J. Filed July 20, 1904.

804,126. Railway Switching and Signaling Apparatus. Winthrop K. Howe, Buffalo, N. Y., assignor to the Taylor Signal Company, same place. Filed March 28, 1903.

804,176. System of Automatic Signaling for Electric Railways. Fitzhugh Townsend, New York City, assignor to the General Railway Signal Company. Filed Aug. 1, 1905.

Electric Lights and Appliances.

803,819. Bracket-Arm for Incandescent Electric Lamps. Hiram L. Getz, Marshalltown, Ia. Filed May 17, 1904.

Electrical Machinery and Apparatus.

803,811. Power-Transmission Device. George A. Cutter, Nashua, N. H. Filed Aug. 14, 1903.

803,825. Trip-Coil for Circuit-Breakers. John D. Hilliard, Jr., Schenectady, N. Y., assignor to the General Electric Company. Filed Feb. 13, 1902.

803,834. Control System. Carl W. Larson, Schenectady, N. Y., assignor to the General Electric Company. Filed April 17, 1905.

803,845. Transmission-Gearing. Charles E. Neal, New York City. Filed March 30, 1905.

803,853. Brush-Holder. Henry G. Reist, Schenectady, N. Y., assignor to the General Electric Company. Filed March 26, 1904.

803,898. Electric Switch. Arthur E. Handy, Providence, R. I., assignor to the Rhode Island Elevator & Machine Company. Filed Oct. 20, 1904.

804,045. Electric Welding Clamping Device. Adolph F. Rietzel, Lynn, Mass., assignor to the Thomson Electric Welding Company. Filed Nov. 16, 1903.

804,070. Electrical Fuse-Plug. George B. Thomas, Bridgeport, Conn., assignor to the Bryant Electric Company. Filed May 22, 1905.

804,156. System of Electric-Motor Control. Charles A. Mudge, New York City. Filed March 2, 1905.

Telephones and Telephone Apparatus

803,676. Telephony. Francis W. Dunbar, Chicago, Ill. Filed Nov. 12, 1904.

803,856. Telephone System. William A. Robinson, South Kortright, N. Y. Filed Feb. 18, 1904.

803,890. Telephone Night-Watch System. William Geckler, Rochester, N. Y. Filed Oct. 17, 1904.

803,980. Telephone-Holder. Charles H. Borden, Stamford, Conn. Filen March 1, 1905.

804,077. Telephone-Exchange System. Harry G. Webster, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed May 7, 1903.

804,103. Telephone Switchboard Apparatus. Thomas V. Davis, Kansas City, Mo., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed April 4, 1904.

Miscellaneous.

803,544. Apparatus for Refining Lead by Electrolysis. Anson G. Betts, Troy, N. Y. Filed March 18, 1904.

803,569. Induction Transformer for Wireless-Telegraphy Receiving-Stations. Eugene Ducretet, Paris, France. Filed March 2, 1904.

803,684. Instrument for Converting Alternating Electric Currents into Continuous Currents. John A. Fleming, London, Eng., assignor to the Marconi Wireless Telegraph Company of America. Filed April 19, 1905.

803,795. Electric Heating Device. George E. Stevens, Lynn, Mass., assignor to the General Electric Company. Filed Feb. 15, 1904.

803,816. Insulating Material. William L. R. Emmet, Schenectady, N. Y., assignor to the General Electric Company. Filed Nov. 24, 1900.

803,836. Vapor Electric Apparatus. Alexander D. Lunt, Schenectady, N. Y., assignor to the General Electric Company. Filed May 12, 1904.

803,936. Electric Pump. John C. Stokes, Mansfield, La. Filed Feb. 28, 1905.

803,973. Insulator. George M. Bemis, Readsboro, Vt. Filed June 11, 1904.

804,040. Electrically-Operated Door-Opening System. William T. Platt, St. Louis, Mo. Filed March 7, 1904.

804,114. Electrical Rosette. Gilbert W. Goodridge, Bridgeport, Conn., assignor to the Bryant Electric Company, same place. Filed Nov. 21, 1904.

804,115. Electrical Insulator. Gilbert W. Goodridge, Bridgeport, Conn. Filed May 5, 1905.

804,182. Metallic Circuit for Operating Signaling Devices. Albert K. Andriano and Hermann Herbstritt, San Francisco, Cal. Filed March 6, 1905.

804,189-190. Apparatus for Measuring the Length of Electric Waves and Instrument for Making Electrical Measurements. John A. Fleming, London, Eng., assignor to the Marconi Wireless Telegraph Company, Limited, same place. Filed Feb. 8, 1905.

THE TELEPHONE WORLD.

Victory for Independents.

Uniontown, Pa., capitalists, headed by J. V. Thompson, have purchased the property and rights of the Carmicheals Telephone Company at Carmichaels and Jefferson, Greene County. The acquisition is counted on as a big victory for Independent concerns in that section, owing to the fact that the Bell Company succeeded recently in purchasing the property and rights of the South Bend Telephone & Telegraph Company.

Aside from obtaining the exchanges the company by the contract comes into possession of the franchise for an exchange at Waynesburg, which was granted in 1897. The Carmichaels Company had toll lines to Masontown, Fayette County, and within one mile of Waynesburg. The loop will be completed and the exchange at Waynesburg will be built at once.

The new company will affiliate itself with the Pittsburg & Allegheny of Pittsburg, the Tri-State Company of Uniontown and the National Company.

The Pacific Telegraph & Telephone Company of Oakland, Cal., has been granted permission by the board of public works for a period of 30 days to trim trees within the city limits where such are in contact with wires already in place, or where new wires are to be placed, on the condition that the trimming should be done by an expert to be approved by Head Gardner Lamond, and be trimmed to the entire satisfaction of the head gardener.

The certificate of incorporation of the East Concord, N. Y., Telephone Company has been filed in the office of the county clerk. The company is capitalized at $5,000. It will run a line through Concord, Sardinia and Colden. J. L. Smith, Samuel D. Vance, Ward H. Marse and Fred T. May of East Concord, George J. Domes and A. E. Spencer, of Sardinia and L. A. Vaughn of Concord, are the directors.

Recent news from Terre Haute. Ind., states that the Citizen's Telephone Company has ordered plans and is now asking for bids for the construction of a modern exchange building. The controlling interest of the company has been secured by the Kinloch people of St. Louis, and the new management anneunces that many improvements will be made.

The South Porto Rico Telephone Company has been incorporated in Portland Me., to build and operate telephone lines. Its capital stock is $30,000. The officers are: President, B. L. Cram; treasurer, A. F. Pike; clerk, C. D. Booth, all of Portland.

The Texas & New Mexico Telephone Company of Las Cruces, N. M., capitalized at $15,000, has been granted a permit to do business in Texas, with its principal office in El Paso.

The Harrison County Telephone Company of Cadiz, O., has increased its capital from $50,000 to $100,000.

Telephone statistics show that almost 20,00,000 persons use the telephone daily.

New Exchange to be Erected.

The Independent Union Telephone Company of Albany, N. Y., will erect a two-story long-distance exchange in Howard street within the next month or so. The work has already been arranged for. Ground will be broken for the new building at once, and the structure will be rushed to completion. It will cost $15,000.

The increased demands upon the long-distance service of the Home Telephone Company made it necessary that additional room be supplied to its office force and to that end it was thought wise to erect a separate building where the long-distance service would be exclusively cared for.

Try to Prevent Telephone Deal.

The hearing on the application in the Wayne Circuit Court for a permanent restraining order to prevent the sale of the Independent Co-operative Telephone Company to the New Home Telephone Company, organized by St. Louis capitalists to develop the Detroit, Mich., Independent field, has been put over until November 20, Judge Mandell having issued a temporary restraining order.

Work will be started at once on the telephone conduits in Chattanooga, Tenn., which will be constructed along certain streets of that city. The contract for the entire job has been let to G. M. Gest, of New York. It is the expectation that the work will be completed by January 1, when all lines and cables on streets traversed by conduits will be placed underground.

The petition of the Atlanta, Ga., Telephone & Telegraph Company for the right to place beneath various streets underground conduits was lately approved by council's committee on electric lights. The conduits, however, can only be used for telephone and telegraph purposes exclusively, except on such terms and conditions as the general council may hereafter impose on petitions therefor.

The delay in the work of remodeling the Athens, Ga., telephone exchange, has been caused by the delay in the shipment of the cables that are to be used in the new system. They were promised by the manufacturers last August, but they have not yet been delivered.

The Bell Telephone Company of Philadelphia, Pa., and the American Telegraph & Telephone Company of New York City, are placing 75,000 miles of wire underground between Wilmington and New York.

The Gate City, Va., Telephone Company has the following officers: President, O. H. Gobble, Clinchport; vice-president, W. D. Smith; secretary and treasurer, J. M. Minnich, of Gate City. The capital stock is $5,000.

In Gouverneur, N. Y., the proposition to issue $25,000 bonds for a municipal telephone system will be submitted to a vote.

Telephone Bids Wanted.

Sealed proposals will be received at the office of the engineer, United States Reclamation Service, Billings, Mont., until December 15, for installing a telephone system having eight or more telephone stations and 22 miles or more of pole line. Particulars may be obtained by application to the Chief Engineer of the Reclamation Service, United States Geological Survey, Washington, D. C., or to Robert S. Stockton engineer, Huntley, Mont.

Bids are being received by the Independent Telephone Company of Council Bluffs, Ia., for the erection of a new exchange building.

Since the Lewiston, Me., board of mayor and aldermen refused to grant the New England Telephone & Telegraph Company's petition for certain rights and privileges in regard to constructing telephone lines within the city limits, there has been considerable talk from time to time ard more than one inquiry has been made by Lewiston taxpayers to know just what the city is getting in return for the franchise and liberties that the New England Telephone Company is enjoying in Lewiston.

O. L. Barger is at the head of a telephone company that has petitioned the Marion, Ind., council for a telephone franchise. The petitioners state that, if granted, an automatic telephone system will be established. The company proposes a service rate not to exceed $1.75 a month for residence telephones and $2.75 for business telephones.

The Attalla, Ala., city council at a recent meeting refused by a unanimous vote to grant the Independent Telephone Company a franchise. It was claimed that the present company was giving a good service and that two companies would increase the expense to the people.

News from Stamford, Conn., states that the Southern New England Telephone Company has purchased a lot of land in Gray Rock Place and will begin immediately the erection of a building for a new local exchange. A switchboard for 3,000 instruments will be installed in place of the present 600-instrument board The building will be completed next spring.

The new switchboard for the Telephone Exchange has arrived in Galveston, Tex., and work on its installation is expected to begin soon. It is thought that it will require some eight weeks to complete the work of installation. Mr. Chambers states that he hopes to have the new system in working order by the beginning of the new year.

The Winnebago County, Ill., Telephone Company has completed the rebuilding of its line in Rockford. The wires have been placed on taller poles, cables have been put in to do away with some of the single wires and all the latest improvements have been made.

The Walker Telephone Company of Shamrock, Tex., capitalized at $10,000, has been incorporated by J. E. Walker, Barnett Blossom and Rea Blossom.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Baldwin, Kan.—The proposition to issue $10,000 in bonds for a municipal electric light plant and also $2,500 for a city hall was lately carried. A maximum meter rate of 12 cents per 1,000 will be adopted.

Benton, Pa.—Definite steps have at last been taken towards bringing the Benton electric light plant into reality. The company has engaged W. O. De Witt, of this town, as consulting engineer, and he will at once prepare plans and specifications for the erection of the power house.

Broken Bow, Neb.—The much longed for electric light plant seems to be assuming a somewhat definite shape.

Cape May, N. J.—The Cape May Light & Power Company is prepared to extend its electric lighting system to Rio Grande, seven miles above here, supplying light to Lower Township and all villages along the road.

Cannon Falls, Minn.—A deal has been completed by which the Cannon River Electric Power Company of this place has become the owner of the Northfield Light, Heat & Power Company. The plant of Northfield will be managed by its present owners for a year, when it will pass into possession of the purchasers. Power for the plant at Northfield and also the local plant will eventually be transmitted from the dam to be built across the Cannon River, one mile west of the Falls.

Clinton, Miss.—This town contemplates issuing $2,000 of bonds for extending the waterworks and electric light plant. H. C. Joyner, mayor.

Courtland, Ala.—Lawson, Sykes & Co. want prices on machinery and equipment for an electric light plant.

Davis, I. T.—J. B. Dickinson will erect an electric light plant here.

Dayton, Tenn.—C. F. Dowker, of Grandview, has purchased of Thomas E. Stone the city electric light plant and is now in charge,

Frankton, Ind.—The water and electric light plant here will go into the hands of a receiver as soon as one is appointed and qualifies.

Joplin, Mo.—There is promise of increased electric lights for the streets of this city in the near future.

Kinsley, Mich.—George Raff, Jr., has the contract for installing the electric lighting plant in this city.

Kutztown, Pa.—The Keystone Electric Light, Heat & Power Company has reduced its rates of lighting private and business houses, from 10 to 7, and probably 6 cents per thousand kilowatts. This change was created through the competition of the borough electric plants.

Lexington. Ky.—Architect Richards, of Columbus, O., has submitted plans and specifications for an electric lighting and power plant, which is designed to furnish light and power for the entire block bounded by Mill, Upper Main and Water streets.

Little Rock, Ark.—A waterworks and electric light plant will be constructed at North Little Rock. Address C. J. Humphreys, 104 East 4th street, waterworks commissioner.

Wallingford, Conn.—The electrical commissioners are in receipt of a communication from representative citizens of Yalesville in reference to holding a meeting relating to the introduction of electricity from the borough's municipal plant for the lighting of the streets of Yalesville.

STREET RAILWAYS.

Asbury Park, N. J.—The property, franchises, etc., of the Atlantic Coast Electric Railway Company, which system extends from Pleasure Bay to Sea Girt, were lately sold in foreclosure proceedings. The purchaser was Adrian H. Joline, of the law firm of Butler, Notman & Joline, New York, and the price $700,000.

Bozeman, Mont.—There is good ground for believing that the project for an electric road for the Gallatin Valley is at last under consideration.

Cairo, Ill.—The Kentucky & Ohio River Interurban Railroad Company has increased its capital from $25,000 to $250,000. The company proposes to build an electric interurban line from this city to Paducah.

Clarksville, Tenn.—There is a probability of an electric line being built between this city and Hopkinsville, Ky.

Columbus, O.—The Elkins-Widener Syndicate is said to be negotiating for the purchase of the electric line now building between Zanesville and New Philadelphia.

Danbury, Conn.—It is understood that plans are under way to build a trolley line from Woodbury to this city, running through Sandy Hook, Newtown and Bethel, and at the latter place connecting with the Danbury & Bethel trolley road.

Easton, Pa.—The trolley line between this city and Washington, N. J., is now assured. For further information address T. Hay, president of the company.

Elizabeth, N. J.—A meeting of a number of local capitalists was lately held and the first steps taken toward the formation of a new trolley building company.

Hot Springs, S. D.—Congressman Eben W. Martin is working for a 12 mile trolley line and a lighting plant to be owned by the United States Government.

Indianapolis, Ind.—The Chicago, Kankakee & Lafayette Southwestern Traction Company has been incorporated with a capital of $100,000. The proposed new road is to run from Lafayette, Ind., to Kankakee, Ill.

Portland, O.—Philadelphia and local capitalists have formed plans for an electric line from this city to Salem.

Pottsville, Pa.—The council has granted the Pottsville Union Traction Company a franchise to build a trolley road here. The system will extend from Shenandoah through Frackville and St. Clair to this place.

Rochester, N. Y.—The Buffalo Pole Line & Constructing Company began the preliminary work of electrifying the West Shore Railroad between this city and Syracuse last week. The work involves an expenditure of about $550,000, and must be finished, according to contract, March 1 next.

Salina, Kan.—A trolley line for this city has been advocated by Mr. Burkholder.

Spencerport, N. Y.—Work is now being pushed on the electric road in this city.

Toledo, O.—The Gardner Construction Company, which has the contract to build the Toledo & Cincinnati Electric Line, will also erect the stations en route and other buildings as may be needed, including power plants and the like. The company, however, will not consider plans for several months yet, as it has but just began on the construction of the railroad.

Waterville, N. Y.—A meeting of the village board of trustees was lately held for the purpose of considering the application of Messrs. McBride and McAdam for a franchise on behalf of a proposed company to be formed for the building, equipping and operating of a trolley road over Mill street.

POWER PLANTS.

Los Angeles, Cal.—The Kern-Rand Company, a corporation recently formed under the laws of Arizona, and having offices in this city, is planning the erection of a power house on the south fork of the Kern River, and the construction of an electrical transmission line to Randsburg. J. W. Eddy is vice-president and general manager.

Milwaukee, Wis.—Architect C. F. Ringer has drawn plans for an electric power plant to cost $6,000.

Owingsville, Ky.—According to reports received here a syndicate of Eastern capitalists is preparing to install a big electric light plant at Rockcastle Falls, in the Rockcastle County Mountains, expecting thereby to furnish light and power for that section of the State. The intention is to harness the falls and save the power that is being wasted.

Utica, N. Y.—The Hudson River Electric Company is now engaged in the erection of a transmission line from its sub-station at Ballston to this city which will probably cost in the neighborhood of $250,000 and extend a distance of about 125 miles.

BIDS WANTED.

New York City.—The War Department, through the depot quartermaster here, is inviting sealed proposals until November 20, for furnishing 55,000 incandescent electric lamps. Proposed blanks and detailed information will be furnished upon application to Major Bingham, Army Building, 39 Whitehall street, New York City.

Washington, D. C.—The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until November 28, for furnishing Eastern Navy Yards with the following electrical supplies: Schedule 224, arc lamps, wire conduit, panel boards, electric clock, electrical supplies; schedule 225, micanite; schedule 227, motor, electrically driven grinders and drills. Blank proposals and full information can be obtained at the Navy Pay Office in New York or upon application to the Bureau in this city.—On December 12 the Bureau will open bids for furnishing Western Navy Yards with the following: Schedule 230, arc lamps, electrical supplies; schedule 231, storage battery outfit, generating set, transformer; schedule 233, motor. Blank proposals can be obtained upon application to the Bureau in this city.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅜@16½c.; Lake 16⅜@16⅝c.; casting, 16⅛@16⅜c.

It is announced that a meeting of the directors of the Chicago Subway Company will be held in Jersey City this week.

It is estimated that shipments of steam turbines for the present year will aggregate about 330,000 kw., valued at about $12,000,000.

At the annual meeting on Monday of the stockholders of the New York City Railway Company the retiring directors were re-elected.

A Philadelphia party has the contract to build the Windsor, Essex & Lake Shore Rapid Railway, an electric road along Lake Erie, to be 125 miles in length and to cost about $2,500,000.

The statement from the General Electric Company that its business is now 40 per cent. greater than last year does not imply that its business for the current fiscal year will exceed that of 1904 by 40 per cent.

The travel on the Subway and Manhattan Elevated lines in New York has increased largely since October 1, and the average increase for the whole system over last year is at the rate exceeding 200,000 passengers per day.

The American Railways Company (Philadelphia) directors have declared a regular quarterly dividend of 1¼ per cent., payable December 15 to holders of record November 29. Books close November 29 and open December 6.

The Tonopah Electrolytic Gold and Silver Reduction Company was recently incorporated at Camden, N. J., with a capital stock of $100,000. The incorporators are H. Gilbert Coyle, J. Shock Summers and Wilfred B. Wolcott.

The stockholders of the Metropolitan Securities Company of New York will hold their annual meeting on December 13 and the annual meeting of the stockholders of the Metropolitan Street Railway Company will be held on December 4.

The financial statement of the Massachusetts Electric Companies for the quarter ended September 30 shows an increase in gross earnings of $83,100 and in net of $56,800. The surplus after charges is placed at $708,000, an increase of $92,400.

The Catskill Mountain & Mohawk Valley Railway Company has been incorporated at Albany, N. Y., with a capital stock of $2,000,000 to construct and operate an electric road 78 miles long in Greene, Delaware, Schoharie and Otsego counties.

The United Gas Improvement Company of Philadelphia has obtained control from Brown Bros. & Co. of Baltimore of the Philadelphia Company of Pittsburg, which has the lighting and street railway franchises in Allegheny County.

The directors of the General Electric Company have not yet reached a decision as to how much of the $11,674,500 new authorized stock will be issued at once or the price at which it will be sold to stockholders. It is likely that an announcement bearing on the plan will be made this week.

Col. A. Loudon Snowden of Philadelphia, president of the Electric Company of America, says that the executive committee is considering the making of a 10 per cent. stock allotment at par, but no action has yet been taken on the subject. This would increase the capital of the company about 40,000 shares. The proceeds would be used to pay for additional properties that the company might conclude to take over.

EDITORIAL NOTES.

Submarine Traffic by Means of Electricity.

Ten years from now a large part of the population of New York, New Jersey and Long Island will travel underground. Ten years from now subterranean and submarine entrances and exits will characterize Greater New York as the city of tunnels. The custom of traveling overhead will imperceptibly change into a custom of traveling underground. Traffic will be carried on in all weathers, not only beneath the foundations of New York's skyscrapers, residences and streets, but beneath the very beds of the rivers that isolate her from the mainland. The city will not be an island surrounded by water, but a city whose highways will lead into the heart of New Jersey, into the heart of Long Island and away north to the now rustic districts along the Hudson River.

Expansion from the active center will be a practical, a commercial and in many respects a social necessity. Old New York will radiate into a substantial new New York. This development will receive its greatest stimulus from the fact that all districts now across the river, on either side, will actually become a part of the solid ground of New York, the greatest influence of all being the tunnels under the East and Hudson Rivers respectively. Not one or two, but many tunnels, which in place of bridges, provide a better means of effecting this highly desirable connection. The latest reports show that the construction company has about completed its work, and the public will be invited to walk dry shod, for the first time in the history of either State, from Jersey ground to New York. The idea is to give the people an opportunity of inspecting the results of a tedious and expensive, not to say dangerous venture. It will also create an occasion for comment with reference to the means to be employed to create a long-looked-for and much needed system of rapid transit between the two States.

The conditions that will soon exist will be those developed through what can be rightly called submarine traffic by means of electricity. And it is to be distinctly understood that the great possibilities this enterprise will arouse on both sides of the river are entirely due to the means employed to make it a pronounced success. As they have been planned these means are entirely electrical in nature. The cars, the lighting, the signaling and heating will be entirely done by electricity. The tunnel will only be endurable in fact, for the obvious reason that electricity is to be the basis for all operating mechanism.

The point of greatest interest is not, however, the mere construction of the tunnel. This it seems, like the tunnel through the Alps, the one under the Thames, or any other instances that might be referred to of borings above or below the water, is a systematic operation. The results are to be expected in the course of time. But the secondary consequences of such constructive work are widespread and more than locally important. They are of immense importance because they establish certain facts of a scientific, political and civic nature. They are to date the best of evidence in favor of the use of electricity for cities so situated that a river as it were cuts them in two. New York is only one of many cases of this kind, and it is fortunate that the times are ripe for the projects completed or incomplete that will so greatly add to its growth. There is little doubt that the actual operation of the tunnels beneath the East and Hudson Rivers will but serve to show the immediate and pressing need for more. They are another example of the tremendous gains the opening years of this century have made in having electricity to serve so remarkable a purpose—its use as a guarantee of at least light, power and breathable air for nearly an unventilated mile beneath the river's bed.

Electro-Zincing Versus "Sherardizing."

The London Society of Engineers was on November 6 entertained by Mr. Sherard Cowper-Coles with an interesting paper on "The Metallic Preservation and Ornamentation of Iron and Steel Surfaces." After describing the process of hot galvanizing the author dealt with electro-zincing, or cold-galvanizing, which consists of electro-depositing zinc from aqueous solutions. A regenerative process was then described, particulars being given of the way in which zinc dust is employed to regenerate the electrolyte, and how the voltage between the electrodes is reduced by employing compound anode and cathode bars.

Mr. Cowper-Coles devoted a great part of his paper to a description of his own new process of dry galvanizing or "Sherardizing." This process, he said, had been found to be much cheaper than hot or electro-galvanizing, as there is no waste of material, whilst the expenditure of fuel is small and the plant simple and inexpensive.

A remarkable feature of this process is that iron and steel can be coated with metallic zinc, by merely bedding it in zinc dust in a drum, placing it in a furnace and raising the zinc to a temperature several hundred degrees below the melting point of that metal. Zinc dust consists of small particles of zinc coated with a film of oxide, and is produced by zinc distillation processes and must not be confused with zinc oxide.

When the drum has been charged with the articles to be treated and zinc dust, it is placed in the furnace which is heated to 500 or 600 degs. F., which is some 200 degs. below the melting point of zinc, the thickness of zinc coating being dependent on time and temperature. On opening the drum the articles are found to be covered with a silvery coating of zinc which has become alloyed or amalgamated with the iron surface.

A description was given of the application of this process for inlaying and ornamenting metals. It has also been found useful for case-hardening copper and coating aluminum previous to electro-plating, also for coating bolts and nuts, as the zinc is evenly distributed so that the threads do not require re-cutting.

Electrical and maintenance engineers of the Pennsylvania Railroad are looking into the practicability of burying the telegraph wires along the main line of that road.

◆

The Swiss Federal Council is now considering the possibility of using electricity as the traction force in the Simplon Tunnel instead of steam.

◆

President Blood of the National Electric Light Association has appointed Mr. T. C. Martin editor of "Progress," to report to the next convention of the association.

◆

The municipality of Berlin, Germany, has voted to build an underground railroad from the north to the south of that city. The line, which will cost about $13,750,000, will be electrical, and will be operated by the city. The measure still requires the sanction of the town council.

◆

The Electrical Trades Exposition Company, which will hold its first annual show in January at the Coliseum in Chicago, has sold nearly one-half of the available 38,000 square feet of floor space.

◆

A recent cable dispatch says the London County Council has decided to introduce a bill in Parliament under which the Council will construct a plant to supply all the electrical energy for London and the suburbs. The cost is estimated at $40,000,000.

◆

One of the problems which confronts the telephone engineer, says the "Electrical Engineer," London, is to obtain a cable on which the losses occurring in the line may be minimized, and one which may be at the same time commercially possible. Experiments, however, have been made on a new type of cable in Sweden, and the results are said to be extremely favorable. In manufacturing these cables, the intention had been to reduce their capacity to a minimum by passing the bare copper wires through perforated disks of insulating material and introducing the cable thus formed into an iron tube. The distance of the two conductors of the same line is 1.7 mm., that of two lines 2.8 mm., and the distance of the conductor and iron sheath in the most unfavorable case 5 mm. By this arrangement the capacity of the internal conductors of 2 mm. diameter was reduced to 0.00985 microfarad for 1 km. and that of the outer conductors to 0.0182 microfarad per kilometer. The copper wires are wound helicoidally to avoid induction effects. If the above distances be increased to 20 mm., 36.5 mm., and 10 mm. respectively, the capacity will be 0.00935 and 0.0125 microfarad.

The "Pyrophone" is a new automatic fire detector, for which it is claimed that it makes the detection of fire in its earliest stage certain, makes false alarms impossible, gives a "danger call" preceding each fire call, and requires no fixed degree of temperature in order to give an alarm. The apparatus consists of a small U-shaped glass tube half filled with mercury in each end. One branch of the tube is exposed, while the other is covered with insulating material. When there is a sudden rise of temperature the liquid in the non-protected branch expands, thus driving the mercury downwards below a platinum wire which enters the tube and causes a danger signal. If the rise of temperature continues the mercury still falls lower, and below another platinum wire, breaking the circuit and causing a fire alarm. The indicator board shows "trouble," "danger," "fire," "earth" and "battery" disks, thus providing for every emergency.

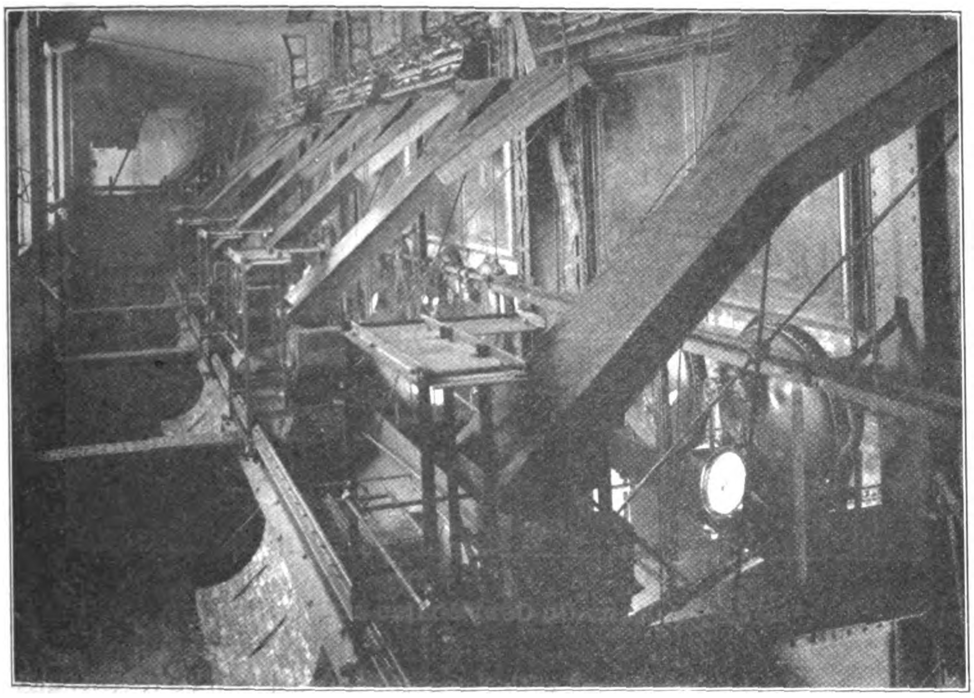
For some weeks past the French War Office has been engaged in conducting experiments with a view to securing reliable communication for military purposes between Paris and the eastern garrison towns by means of wireless telegraphy. Though many difficulties had to be encountered, these were eventually overcome, and after the system had been extended as far as Vardun and Chalons, the important stronghold of Belfort was furnished with apparatus for wireless telegraphy. According to the "Electrical Engineer," London, there is now complete and permanent communication between Paris and all the eastern garrisons.

ENGLISH AUTOMATIC GRAIN AND COAL WEIGHING DEVICES.

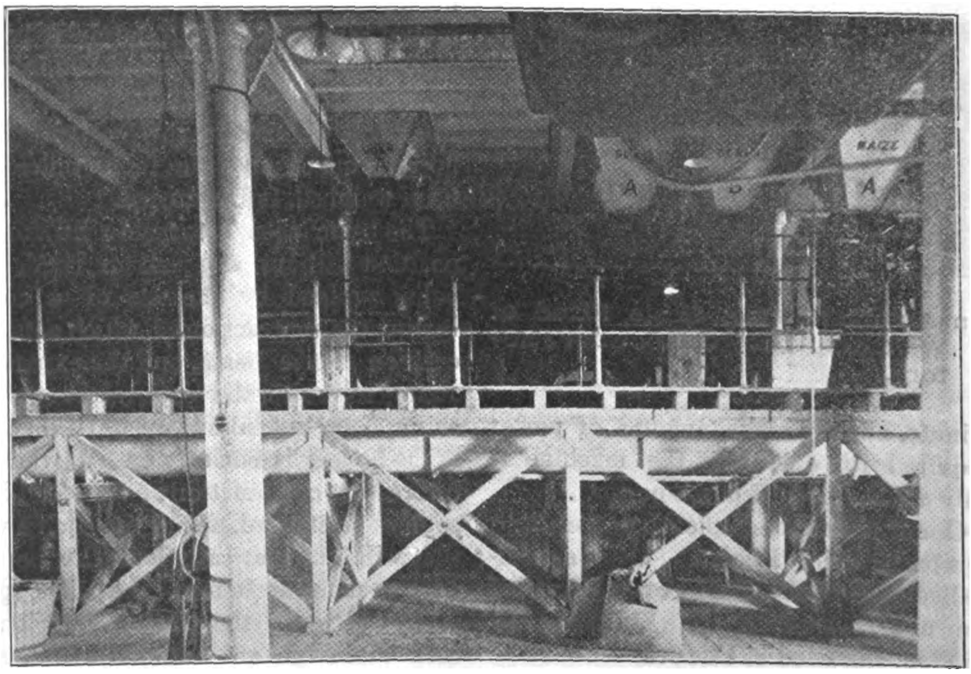
BY FRANK C. PERKINS.

Automatic coal weighing machines are now being largely employed, not only in power stations, but also at coal mines, the scales automatically weighing and recording the small coal from the mines working in connection with the coal washing plant. These machines are in operation at Chesterfield, England, at the coal mines of the Stavely Coal & Iron Company, and are also utilized at factories and manufacturing plants, machines of this type for this purpose being employed at a royal gunpowder factory in England. Automatic oil and liquid weighers are also being constructed and are in daily use at the British Oil & Cake Mills at Hull. These automatic oil scales are fitted with self-registers which count every weight made and are arranged with hoppers, having each a capacity of one-half ton of oil per each discharge. One of the illustrations show an automatic grain scale arranged for the weighing of oats, bran, beans and maize before being discharged into bags for shipment. Some of these automatic grain scales have a capacity for weighing 200 tons per hour, and form only a small part of the automatic labor-saving devices now utilized so extensively in every line of service at the present time.



Fourteen Travelling Coal Scales at Neasden Power Station.

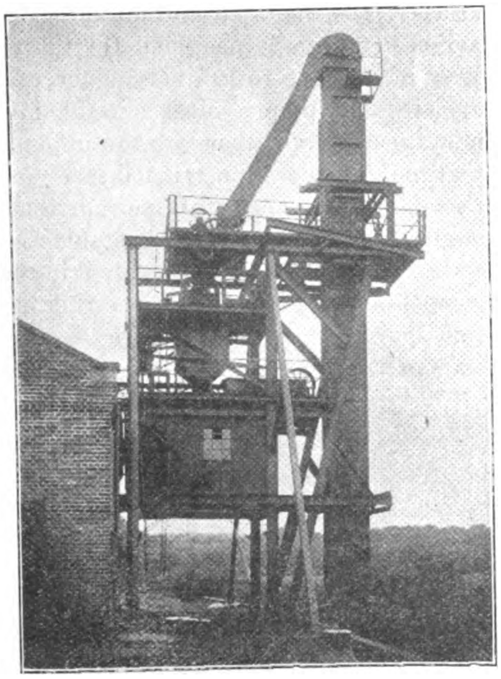
In modern power stations the coal handling apparatus is considered fully as important as any part of the power house equipment, and not only are automatic hoists and coal conveyors installed for bringing the coal automatically to the storage bin over the boilers without hand labor, but automatic coal scales are now utilized extensively for weighing the coal as it is utilized by the boilers. The weighing machines at some electric lighting stations are fed by grabs and are capable of weighing 40 tons of coal per hour. The accompanying illustrations show the automatic coal scales weighing the fuel to the boilers in modern English power plants. There are eight or more of these machines weighing coal to the boilers of the power station at Newcastle-on-the-Tyne Corporation, and double this number of scales are at work in the two power stations of the Corporation Tramways at Glasgow. These automatic scales are constructed at Birmingham by W. & T. Avery Co., Limited. There are 14 traveling automatic coal scales at Neasden power station, while other automatic weighing devices have been utilized advantageously for a considerable length of time at the power houses at Black Pool, Sheffield and other English electric plants as well as at manufacturing plants where fixed automatic coal scales are often utilized, as at the Waltham Abbey Gunpowder Factory. The weighing machines are sometimes fitted with sight registers, which show the weight from each discharge of the grab. They are also fitted with self-closing and locking doors. These English automatic coal scales are provided with access platforms immediately below the coal bunker, and the coal is delivered from the overhead bunkers to the scale below, which automatically weighs, registers and delivers the exact quantity required by the mechanical stoker attached to the boiler below the scale, one machine being usually supplied to each boiler.



Automatic Scales for Weighing Oats, Bran and Maize.

Electrically operated automatic scales have been specially designed for taking pieces of coal up to 12 inches cube, and they are said to be a most suitable machine for dealing with very large amounts at a time. They are constructed steelyard or lever principle, so that proportional weights may be used, and it is stated that this means a considerable saving in the strength of the supporting structure; some source of electrical energy is necessary, about one-half brake horse-power being required to operate this machine. Automatic coal weighers are also utilized largely with self-registering and closing apparatus. With this arrangement the load comes down intermittently, such as from a crane grab, skip or a tipping truck, and will take practically any sized lumps. The load falls into the receiving hopper which is rigidly supported so as to take the impetus, and from the receiving hopper it drops gently into the hopper below, which is the actual weighing hopper. This action automatically throws a clutch into gear, whereby the poised weight is moved along the steelyard until the balance point is reached exactly the same as in hand weighing.

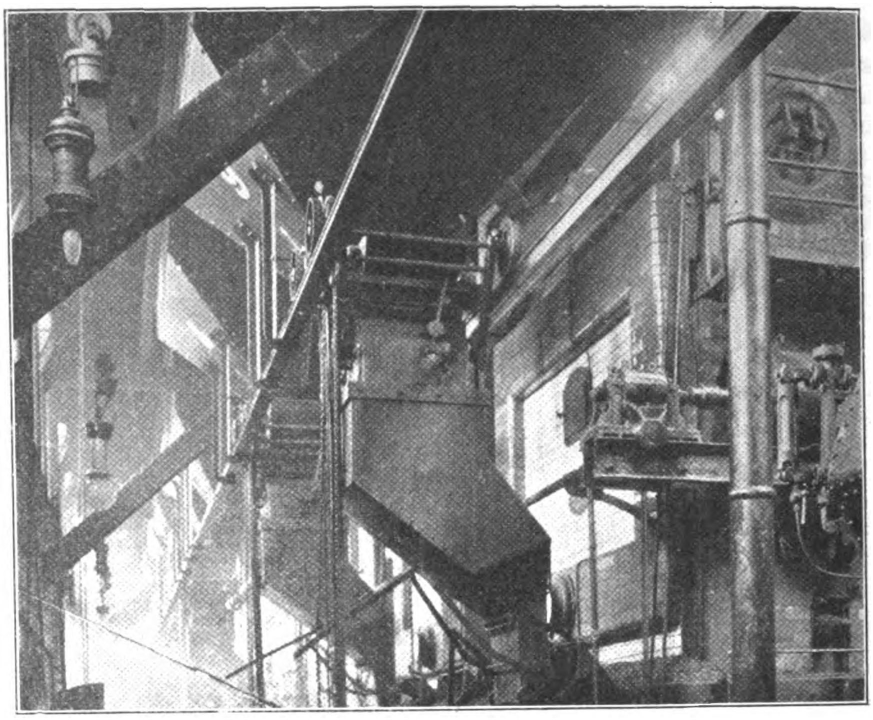
A time cam is so arranged as to now open a door at the bottom of the weighing hopper whereby the coal is released as soon as the load is taken off the machine; the poise weight returns to zero and at the same time the weight is recorded on the dials, and it is added to the total weight of the previous weighing. The machine is then ready for a fresh load, and it is stated that for machines with a hopper capacity of one or two tons the time taken is something under a minute, although the amount of power required for operating the machine is only about one-half horse-power.



An Automatic Coal Scale Fixed at Waltham Abbey Gunpowder Factory.

One of the most complete coal weighing equipments in England has been installed at the Lot's Road Power House of the underground electric railways of London, installed at Chelsea.

The coal is brought in barges to the private dock of the company from the Thames River, and the coal is raised at the rate of 100 tons per hour by a large grab and dropped into the automatic coal scale, the construction of which is such that the dust is continually removed by the action of the working parts.



Avery Automatic Coal Scales at Sheffield.

It is most interesting to see this machine weighing the coal continuously and with perfect accuracy absolutely automatically. The coal enters the machine in a large stream through two large openings until the required weight is nearly obtained, when a moving gate cuts off the supply to a very small stream so that the turn of the scale can be worked to a minimum. When the beam turns a trigger is moved, which causes the supply to be immediately shut off, and when the locking gear of the hopper containing the fuel is liberated, a door in the bottom of the hopper opens and the fuel, which has been weighed, is discharged.

The beam then returns to its former position without any jerk or thud, this being avoided by the use of a coiled spring, the contraction of which acts as a cushion to the beam, and the expansion acting to reopen the gate, although this action does not take place until the door of the hopper is entirely closed, when an interesting combination of two dead-lock cobbles is affected, acting in such a way that will automatically lock the hopper door a moment before the feed gate is opened. At the Chelsea Station at each discharge an automatic indicator registers the discharge and the exact amount of fuel passing through the machine is thus recorded at the end of a day, week or year, as is desired. A large number of automatic stokers is now being employed in Europe as well as in America, and the practice is becoming general of automatically weighing the coal by machines of this type, as the daily consumption of fuel can be registered without error.

LIGHT, HEAT AND POWER PRINCIPLES.—IX.

BY NEWTON HARRISON, E. E.

The Transformer for Light and Power.—The use of the transformer for light and power has been the means of making the alternating current system highly elastic in character. The value of the transformer as an efficient machine depends upon the extent to which it can meet the following requirements:

First—At no load the primary winding carries little or practically no current, and therefore the waste of energy is very limited when the transformer is not in use.

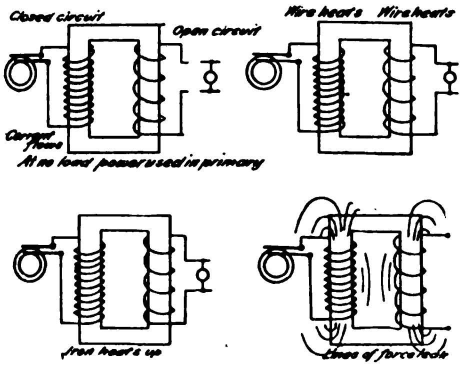
Second—That the losses in the iron of the transformer, due to eddy currents, are very small at all conditions of load.

Third—That the losses in the iron of the transformer, due to the effect of hysteresis, are limited, so as to be within the bounds of a high efficiency at all points of load on the secondary.

Fourth—That the resistance of both primary and secondary windings is such that the heat loss is not excessive at either full load or no load.

Fifth—That there is no magnetic leakage between the poles of the coils, thus causing the lines of force that should enter the cores to pass on the oustide.

Sixth—That at no load the impressed EMF. of the primary and the back EMF. of self-induction are sufficiently equivalent to prevent all but a minimum of current from passing through.



Sources of wasted power in a transformer.

To properly review the influence of the transformer upon electric light and power work it is necessary to form a correct estimate of the extent to which each of its essential elements contribute to the net result. From a general standpoint it may be said that the transformer merely consists of two coils—one called a primary and the other a secondary—wound upon a core of divided or laminated iron. The primary coil is connected to a source of impressed EMF. as it is called. The secondary is connected to the lighting or power circuit, as the case may be.

Mutual Induction.—The effect of one coil upon the other is due to mutual induction. The adjustment of the power entering the primary, so as to affect the secondary, is accomplished by the natural regulative effect of the self-induction in the primary.

It may be stated therefore without equivocation that the actual development of power in the totally disassociated secondary is due to the direct effect of mutual induction. On the other hand, the regulation of the power in the primary coil, through which power adjustments take place not only in it but in all parts of the connected system, is due to the self-induction.

Losses of Power.—The exact source of losses of power in the transformer may be summed up in the following list: First, losses in pressure in both primary and secondary, due to the natural or ohmic resistance of the wire; second, losses of power in watts, arising through the development of heat in the said coils and commonly called the C^2R loss; third, losses in the iron which are due to two distinct causes—(first, the development of minute parasitical currents in the iron itself, which consume energy called eddy currents, and, second, to the effect of hysteresis, caused by the constant reversals of magnetism), all of which combine to raise the temperature of the iron. Thus, influences will be at work to heat the coils, unless provision is made to hold them in check. And in addition other influences are at work to heat the iron, which must be similarly understood and held in check. The alternator generating the current now employed so widely is not one whit more important than the transformer, whose function is that of raising or lowering its pressure. A very efficient alternator delivering, say, 100 kw. to the transformer or transformers in its circuit, may not lose more than 10 per cent. of its energy in the entire process of generation and distribution. Of the 100 kw., about 90 kw. will be on tap for consumers' use whenever required.

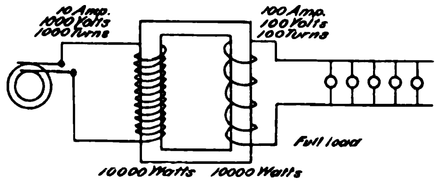
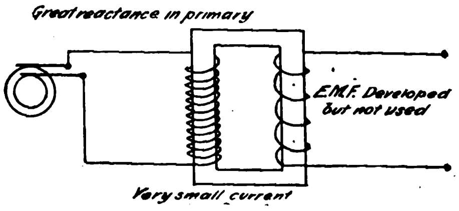
Ratio of Pressures.—The two pressures of the transformer are called the primary electromotive force and the secondary electromotive force. The exact ratio of these two pressures is the exact ratio of their windings in theory and practice. For instance, if 1,000 turns on the primary take 1,000 volts, then 100 volts from the secondary can be obtained by means of 100 turns. The ratio is therefore as follows: EMF. of primary : EMF. of secondary, as the turns of the primary are to the turns of the secondary. A simple rule of this character also presents the facts with respect to the current as well. For instance, if the number of watts in the primary are 10,000 and the current in the primary is 10 amperes, then, as 10,000 watts are practically delivered by the secondary, the current in amperes, at 100 volts pressure, would be 10 times as great, or 100. The rule therefore appears, relating to this, as follows: The current in the primary is to the current in the secondary as the pressure in the secondary is to the pressure in the primary. This is represented by the symbols in the following manner, both with regard to the pressures and windings, as well as the ratios of the currents: $E_p : E_s = S_p : S_s$ as regards the electromotive forces and primary and secondary windings; also $C_p : C_s = E_s : E_p$ as regards the currents and electromotive forces.



Ratio of windings, volts and current in a transformer.

Without Load.—When there is no load the secondary of the transformer is said to be on open circuit, and the current in the primary is at its lowest value. The electromotive force induced in the primary coil through self-induction is so high that only a small difference exists between it and the EMF. sent in from the alternator. This difference of EMF. is useful in keeping the primary coil choked as it were. Under these conditions, namely, of open circuit for the secondary, the primary coil represents a simple case of a highly self-inductive coil in circuit with an alternating current. Its inductive reactance under these conditions is obviously at a maximum. The value of pL is therefore sufficiently high to prevent any but a very small current from operating.

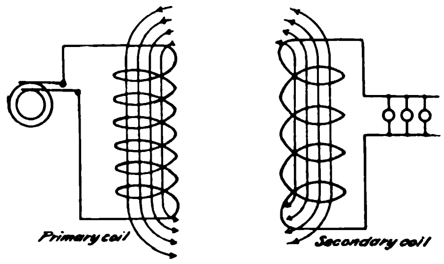


Inductive reactance with secondary open.

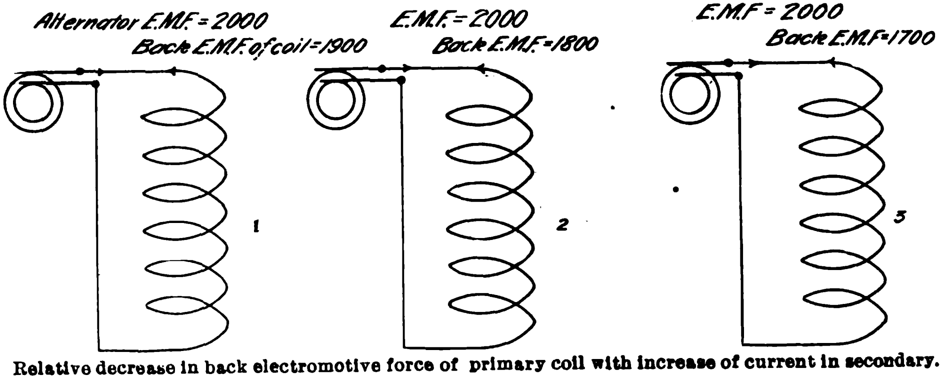
At this point the transformer represents a negligible consumption of power. Should it be otherwise, however, a case exists of where power is being unduly wasted as a consequence of bad design. If 100 transformers are considered, taking on an average of from .1 to .2 of an ampere apiece, the total power consumption at 2,000 volts would be 100 × .1 × 2,000, or 100 × .2 × 2,000, equal respectively to 20,000 or 40,000 watts. The design of a transformer therefore must be such that the waste of power at no load is extremely low, otherwise a power leak or waste will appear which may seriously affect the financial returns. The primaries of the transformers of an extensive system of electric lighting are regarded as costing a definite sum per annum for power losses.

Inventions made for the purpose of automatically cutting out the primaries when the secondary circuits are opened have not proved practicable.

With Load.—When the secondary of the transformer is closed the amount of current flowing into the primary and secondary immediately becomes automatically regulated by inductive influences. Even though the secondary is open, the mutually inductive effect of the primary is such, as to cause electromotive force to be generated in it. In other words, although no current flows in the secondary, it is in certain respects no different from the armature of a generator on open circuit. The field is actively operating, but the conductors of the armature, though generating EMF., cannot cause a current to flow until the circuit is closed. When this occurs in the case of the secondary, when it is being used to generate current for lighting or power purposes, the current flowing in it exercises a reverse magnetic influence to that in the primary. In fact, the effect is such that not only is the amount of magnetism in the transformer cut down, but the back EMF. of the primary is necessarily cut down, and in consequence the EMF. of the secondary as well. The case, as here presented, is that of the closing of the secondary, causing current to flow in that coil, thereby magnetizing its core in a reverse direction to that caused by the primary, thus cutting down the magnetization of the primary and permitting more current to enter it. The fact to be noted, however, is that a very slight difference between the EMF. impressed upon the terminals of the primary by the alternator and the EMF. induced within the coil of the primary through self-induction, will be quite sufficient to send a greatly increased current through the primary. Regulation here, in this respect, is very delicate, and it is evident that both the increased magnetization due to the increased ampere turns of the primary, and the increased but reverse magnetization due to the current in the secondary will very nearly balance. In other words, the magnetization of the primary and the demagnetization of the secondary will be approximately equal. Under these conditions, the magnetization of the transformer iron under all conditions of load will remain practically unchanged.

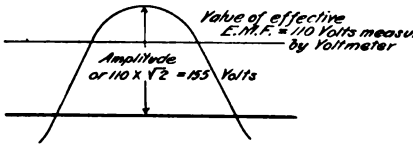


Opposing magnetizations of primary and secondary.



Relative decrease in back electromotive force of primary coil with increase of current in secondary.

Relationship of Primary and Secondary Current.—The current in the primary is controlled by the degree of mutual induction taking place between it and the current in the secondary. The coils are only the mediums through which they operate and affect each other. Their lines of force are the essential and fundamental basis of all reactions. The primary is therefore magnetically as much a part of the secondary, as the secondary is a part of the primary. Each is mutually sensitive to changes taking place in the other. The current in the primary could not increase unless the secondary by its reaction permitted it. It is evident that the only way in which the current in the primary can increase is by a reduction of the difference between its impressed and its back EMF. But to lower the back EMF., it is necessary to reduce the inductive reactance, a thing only possible by reducing the number of lines of force producing it. Under these circumstances, it is evident that the only efficient means to employ (were none other available) would be to reduce the number of lines of force, as they are automatically reduced by the current in the secondary. When the secondary circuit is closed the amount of current flowing through it is dependent upon the amount of resistance in the outside circuit connected to it. For this reason, as more and more incandescent lamps are turned on in the secondary circuit of a transformer, the resistance is reduced more and more, and in consequence a heavier volume of current flows through the secondary coil. As more current flows through the secondary coil, its reverse magnetizing effect to that of the primary coil cuts down the total amount of lines of force to just the extent required to permit only enough extra current to flow in the primary to do the work required. In other words, when the primary gets more current it is because the secondary takes more current. On the other hand, when the primary takes less current it is because the secondary has reduced its quota of current by the turning off of lamp circuits, etc. Both the iron and the copper in these specific cases are merely the mediums which carry the energy employed. In the one case the energy as current, and in the other case the energy as magnetism.



Difference between the commercial or effective pressure and the maximum or amplitude.

Calculating the EMF. of the Coils.—The two electromotive forces of the primary and secondary respectively can be calculated by means of a simple formula embracing the total number of lines of force, the total turns and the frequency. The formula is as follows:

Total lines of force in core = volts $\times 10^8 \div 4.44 \times$ turns of wire $\times$ frequency.

For instance, in showing its application, if the volts required are 1,000, the frequency 100, and turns of wire 1,000, the formula would then represent: total lines of force in core $= 1{,}000 \times 10^8 \div 4.44 \times 1{,}000 \times 100$ equals 225,225. The lines of force in the core would not be very high per square inch for reasons that will be readily made obvious. The calculation of volts, lines of force or turns is manifestly dependent upon the arrangement of the formula. To get turns, the formula is arranged as follows: Turns $= E \times 10^8 \div 4.44 \times$ total lines of force $\times$ frequency. To get volts, the formula reads: volts $= 4.44 \times$ turns $\times$ maximum lines of force $\times$ frequency $\div 10^8$. In this formula, the total lines of force are the maximum created by the current in the primary coil. The volts obtained by this means, however, are the effective volts. The maximum volts divided by the $\sqrt{2}$ equals the effective volts, or the volts read off from an alternating current voltmeter. According to this last calculation, a 110 volt alternating current lighting circuit is supplying an effective or commercial pressure of 110 volts, but a maximum pressure of

$$110 \times \sqrt{2} = 110 \times 1.41 = 155 \text{ volts.}$$

This is called the amplitude of the pressure, and is the highest point reached by the sine wave of electromotive force.

Iron Losses.—The reason why the magnetism in the core is not made high is because of the effects of hysteresis. By some this has been called molecular friction. But it is readily understood as the phenomenon causing energy to be absorbed during the process of magnetization and a reversal of magnetism. The greater the number of lines of force per cubic inch of iron in the transformer core, the greater the energy absorbed in the process referred to of reversing it. Therefore, the magnetization in transformers, is limited to a certain safe maximum. Beyond this point a great waste of power and high temperature in the iron are inevitable. This is called the limit of the the flux density.

EARTHED AND UNEARTHED RADIATORS IN WIRELESS TELEGRAPHY.*

BY W. H. ECCLES, D.SC.

Recent commendations of certain new Lodge-Muirhead wireless telegraph stations equipped with insulated oscillators and resonators of the 1897 English patent, make the moment opportune for a brief review of the reasons and facts that have made the use of the earthed radiator almost universal and the use of one unearthed rather exceptional. A plain statement of the present position of the rival cults—the earthed and the unearthed—in the light of widely-accepted theory, can be made and is best made without recourse to mathematics.

In the early days of Hertzian space telegraphy (say 10 years ago) the solution of the signaling problem was expected in the employment of straight beams of electrical radiation. The electric rays used, produced of course in the Hertzian manner, were to be projected in any desired direction and were to be capable of penetrating all obstacles between sender and receiver. Hence it was that radiation of short wave length generated at the focus of a parabolic mirror was the vogue among the "wireless" experimenters of that day. It was probably in an endeavor to get a bigger output of radiation per spark that Marconi in 1895 connected large insulated conductors—storehouses—to one side of his oscillator. Contrary, perhaps, to what he had expected, signals were better when these insulated conductors were lifted to a distance from the earth (and their capacity thus reduced) and better still when the far side of the spark-gap was earthed. In fact, capacity in itself seemed of so little account that the large elevated conductor could be removed and the connecting wire left supported alone in the air without greatly diminishing the strength of signals. Thus Marconi followed Popoff, without copying him, to the use of the plain earthed air-wire, originally designed, it seems, by Popoff for other purposes than wireless telegraphy.

The scientific basis, as we understand it, of these rapid successes of Marconi have been given numberless times. We see clearly enough now that it supports Marconi's own opinion that his success was largely due to the use of the earthed air-wire. It is necessary here to write down once again the virtues, as oscillator and radiator, of the long vertical earthed air-wire. Put shortly, its merits are: First, its great length insures slow vibrations, and therefore long waves; second, it sets the waves up so that the electric force in a wave front is, from the very beginning, in a vertical plane; third, what is partly implied in the last, it attaches to the surface of the earth the free ends of the moving lines of force; fourth, it is a good radiator (and absorber). Long waves are advantageous, largely for reasons connected with diffraction; the setting vertically of the electric force near the earth avoids losses such as would otherwise occur from the generation of profitless currents in the earth's substance; and the attachment of the waves to the earth's surface prevents them straying wholly into space and gives them such guidance (similar to that given by a wire to the current it carries) as enables ranges of hills to be surmounted without suggestion of penetration. But the air-wire's power as a good radiator, valuable at a time when the object was to "get there," has become in this era of syntonic ambition its cheapest fault if it is in itself the whole oscillator; for, as has often been explained, rapid radiation shortens enormously the train of effective waves, if, as must be in the case of the simple air-wire, the energy stored electrostatically, just before each spark, is small. There is no need to do more here than mention that by using a closed (non-radiating) oscillator of great energy capacity to feed a simple air-wire, sustained trains of waves can be emitted and the earthed air-wire thus retained in its old post of honor.

At a very early stage of this story, Lodge seems to have perceived this inadequacy of the simple air-wire for syntonic working; and, at least as early as 1897, was using in preference a symmetrical Hertzian wave-maker. The one at Heysham, for example, consists of two horizontal conducting plane areas about 80 feet square, one vertically above the other, and connected to it by a vertical central wire about 80 feet long. The lower square is about 3 feet from the ground, and, like the upper, is insulated. The vertical wire is interrupted at its middle by a spark gap. This structure is, from its geometrical configuration, a slower generator than a simple air-wire, and gathers before each spark a much greater charge. For both reasons it produces trains of waves more sustained than those of an air-wire. Moreover, it possesses most of the merits of the plain air-wire. It makes very long waves, and it sets them up with their moving lines of force in vertical planes. But it fails in this, that it does not attach the waves to the earth's surface. The waves have to do that for themselves, as they may do when free later on. To compensate for this, however, there stands the complete freedom from earth connection. What this means can only be appreciated by recalling *one*, let us say, of the difficulties that beset the radiator that is earthed—namely, the variability in the goodness of the "earth."

This variation of quality of "earth" did not matter so much in untuned working, but in tuned telegraphy it is more important; and when making comparisons with the Lodge-Muirhead wave-maker we must look to tuned systems. Suppose then, that in a syntonic transmitter the radiator is tuned to the closed feeding circuit when there is a good earth, and that by some means the earth goes bad—i. e., acquires an unwonted resistance. Then, inevitably, foreign overtones, of kind and strength depending on the badness of the earth, are introduced into the vibration. These overtones are produced at the expense of the fundamental by reflection, at the resistance of the pulses descending the air-wire. There is, besides, absorption of energy in the resistance; indeed it has been shown both theoretically and experimentally, that with a certain critical resistance the absorption of the vibrations in the resistance may be extremely rapid. If this last condition is ever happened upon in practice, it must be of serious import even where forced vibrations of the correct period, namely, that of the distant receiver, can be maintained upon the transmitter air-wire by a heavy feeding system behind it. All these considerations apply with equal or even greater force to the earthed absorbing wire of the receiving system. Hence, it will be seen, to be earth-free is something worth striving for. Thus the question is, does the attainment of this desideratum by the Lodge-Muirhead wave-maker compensate fully for the fact that the waves as at first emitted are free, that is, unattached to the earth's surface?

---

*From the "Electrician," London.

If one traces in imagination the movements of the lines of electric force near the Lodge-Muirhead radiator when in action, he concludes that the lines which detach themselves from the conductor to form waves appear as rings situated in vertical planes passing through the vertical central wire, moving outward horizontally with the speed of light and expanding as they go. They will resemble, in fact, the rings familiar to us in diagrams of the ordinary Hertzian oscillator, but will probably be more distorted than those in the pictures and will include a smaller proportion of the whole number of lines of force initially present in the fully-charged oscillator. As each ring moves forward and expands, its lower bend strikes the earth and is reflected or absorbed there. If the earth's surface were of very good conducting material, the lower half of each ring would ultimately be folded up towards coincidence with the upper half. Now, in this process of reflection, the direction of the horizontal component of electric force is reversed. Thus high reflection at the earth's surface would involve considerable strengthening of the waves near the earth—just where strength is wanted. As a matter of working experience, this strengthening by reflection seems not to be experienced at the earth's surface in any degree so completely as has just been indicated; but it is well admitted that the earth's surface cannot be supposed a perfect conductor. The folding up of the lower half of each looped line of force is probably very incomplete. Allowing for this, it seems possible that perhaps one-half of the whole wave energy—the half carried in the lower portion of each ring of force—may be wasted ohmically in the earth comparatively near the radiator. On the other hand, the earthed radiator, placed normally over a conducting sheet (the earth to which it is connected) detaches, in the popular theory, half-rings, which move outwards in vertical radial planes, with their cut ends sliding perpendicularly over the conducting plane. This arrangement seems ideally perfect. But here again the earth's surface is, in reality, not a good conductor. Therefore, in the very act of electrical vibration—which may be interpreted, as is well known, in terms of positive and negative reflections of electricity at the top and bottom of the earthed air-wire—great wastage may occur before the detachment of the waves. In both cases lines of force traveling over a bad conductor must acquire a forward slope which will involve the propagation of energy into the earth, or, to put it in another way, will involve the creation of currents in the earth's substance with consequent ohmic losses. Taking all this into account, however, as well as may be done by these descriptive methods of examining the question, the advantage, on the whole, seems to lie with the earthed radiator. The conclusions we are driven to amount, in fact, to these: That in the case of the Lodge-Muirhead radiator working over the badly-conducting earth a 50 per cent. ohmic loss of the whole output of radiation is possible; whereas with the earthed radiator there are losses in vibrational energy amounting probably to a smaller figure.

SINGLE PHASE RAILWAYS IN EUROPE.

(From our London Correspondent.)

Up to the present there is not in England any example—even experimental, unless it be at Trafford Park where the British Westinghouse Company were going to put down a short section, though we have not heard of its completion—of an electric railway operated on the single phase alternating current overhead collection system. The railways that have so far electrified certain sections have all dropped third or fourth rail direct current working. It is true that the intention of the London, Brighton & South Coast Railway Company to equip a short single phase section in the neighborhood of London was announced some time ago, and that electrical firms of eminence in England and abroad have been engaged upon the consideration of the matter, but so far as the writer knows the contract has not yet been placed, and it will be long before this experimental section will be operating and be affording the railway managers and directors of England that practical data regarding the comparative working of direct current and single phase systems on actual English lines for which they are at present thirsting.

Electrical authorities, however, who have kept themselves fully informed regarding the developments which have been occurring in America and in Continental Europe in single phase traction, are doing their level best to insure for that system an intelligent consideration not only from railway men but from the general public too. Prof. Silvanus P. Thompson, Sir William Preece and other electrical engineering authorities are persistently urging the claims of the overhead conductor method as against the drawbacks attending the employment of live surface conductor rails. The educational influence of all this writing in newspapers, and in the technical press, regarding experience and actual performance in other countries must be very considerable; it is one of those things of which it never will be possible to accurately gauge the extent to which it influences the ultimate settlement.

As this article is being written an issue of the Engineering Supplement of the London "Times" has just appeared (November 1) in which several correspondents engage in controversy respecting the wisdom or otherwise of adopting the third rail for the London Metropolitan. Mr. H. F. Parshall writes, replying to the criticisms of Prof. S. P. Thompson, and remarks that under given conditions either system may be the more advantageous. He says that in an electrical system the third rail is the most reliable and the least troublesome element in the whole traction system. "For heavy traction," says Mr. Parshall, "it cannot be lightly put aside and superseded by something yet to be proved suitable for the same class of work." Sir Alexander B. W. Kennedy writes that "many English engineers, including myself, both believed and pointed out, long before the matter was taken up on the Continent and by Americans, that the single phase system with one overhead conductor was the only probable solution of the heavy railway question, and our opinions seem now to be shared by engineers generally."

The Union and A. E. G. concerns of Berlin (now one organization) were responsible for the first European single phase equipment undertaken. The lines they have equipped with the dates thereof are: (1) Opened August, 1903, 4.1 km. of line between Niederschoeneweide and Spindlersfeld with two motor cars, the pressure being 6,000 volts and the frequency 25 cycles; (2) July, 1904, the 18 2 km. Stubaithal railway with four motor cars, the pressure being 2,500 volts and the frequency 42 cycles.

Next in order there followed the completion of the first portion of the Borinage District Railway, and as this section has been operating for a few months only, and a good many miles are now equipping to complete the scheme, a good deal of interest is being taken in it at the present moment in England. It being the latest representative of such work in Europe, some particulars of the undertaking will be given, but before doing so it should be stated that the short experimental single phase line which the A. E. G. is putting down for the Swedish State Railway Department with a 6,000 voltage, a 25 frequency and two motor cars with 100 hp. motors, is to be completed shortly; the same company is also engaged upon a much larger undertaking, involving the supply of 51 motor cars, with a 6,000 voltage and 25 cycle frequency, for the Blankenese-Ohlsdorf Metropolitan & Suburban Railway.

To return to the Borinage District Railway, one of the chief features of the electric lines is the high frequency employed, viz., 40 cycles. The Stubaithal line was the first high frequency line inaugurated; it employed a current of 42 cycles, and the results which have attended the operation of the system are said to have been so satisfactory that the A. E. G. felt amply justified in employing an almost equally high frequency for Borinage.

The District Railway belongs to the Societe Nationale des Chemins de Fer Vicinaux, which owns all the Belgian District Railways, and controls more than 2,000 kilometers of track. It is interesting to observe that this company has from the first been conspicuous for the adoption of an enlightened policy in dealing with the subject of electric traction. Five of its lines are already so equipped; the heavier lines are still worked by steam, though the company is watching events closely, awaiting the happening of justifying performances to make the change. The first section in this great southern coal mining district of Belgium to use single current, is about 21 kilometers long, but the extensions will consist of another 108 kilometers. It is the intention that this 129 kilometers shall be entirely fed from one point with single phase alternating current at 40 cycles and 6,600 volts. For the present equipment the pressure of 6,600 volts is transformed down to 600 volts (the trolley wire pressure) by track transformers. The extension lines will, however, have a higher tension for the trolley wires, and the necessity of line transformers will in consequence be avoided.

The railway runs chiefly through streets in populous districts, but there is private track in places; for the most part the track is laid single.

Electrical energy for working the system is purchased from the Societe d'Electricite du Borinage, which supplies light and power to the district. The generating station is arranged for high tension three-phase current to meet the requirements of many customers for motor power. The switchboard was arranged for giving a 6,600 volt single phase current to the railway. The generators are star-connected, two larger ones, 40 pole, being so built that they each have a capacity of 375 kva. single-phase current by using any two phases of the star connection, or 375 kva. three-phase current at 40 cycles. There is a smaller generator which has 36 poles, and can deliver 225 kva. single, or three-phase current. All the machines give 6,600 volts as phase voltage. Only two phases of each three-phase dynamo are thus used for working the railway, and this it is claimed to prove that light and power can be obtained, and a single-phase railway worked from one three-phase power station without the necessity of frequency transformers or special single phase machines.

The high tension wires are carried from the switchboard to the distributing tower direct. They are carried from the power station on wooden masts, special double-pole conductors being led from the switchboard to each of the four transformer brick huts, whose positions were chosen with the idea that besides the trolley wires, no further low tension feeding wires should be provided. All four stations work in parallel on to the trolley wire, which is not divided into separate sections.

There being telegraph and telephone earth return lines in the neighborhood the rails are not allowed to be used as a return for the railway current, so double trolley wires are used. They are arranged 90 cm. apart, and are grooved wires of hard drawn circular copper. Double T-iron channels are mostly employed for the masts, and bracket suspensions are adopted wherever possible, cross-pole suspensions only being present in a few cases.

The line pressure being only 600 volts the trolley wires are hung tramway fashion, the new track material of the A. E. G. being used. At one point there is a specially low bridge where the distance between the trolley wire and the rail level is only 3.35 km. To avoid accidents here it is provided that the wires under the bridge shall remain without current when no car is passing through. As the car approaches the bridge the guard closes a special switch which allows the current to run along the trolley wire and after the car has passed through the switch is again opened by the guard.

As to the rolling stock, this is of plain description, for working class traffic is the chief custom. Each car holds 20 persons seated and 20 standing. There are no special trucks, but the axle-bearing holders are fastened direct on to the longitudinal box carriers, which run straight through from one end of the platform to the other. The car body is hung on spiral springs and also supported by long plate springs.

To each car there are two Winter-Eichberg motors (type W E 31B), having a capacity of 40 hp. on a one-hour rating; these are six-pole motors for 40 cycles and 550 volts average pressure. The motors work by means of a toothed-wheel gearing on the axles in the usual manner. The control is effected by series parallel control in connection with a regulating transformer which is suspended on brackets under the floor in the center of the car by means of bolts, the brackets being suspended on the longitudinal car supports.

A train consists of one motor car and two trailers. The motor cars have two current collectors mounted on a strengthened part in the center of the roof of the car, side by side, at a distance of 90 mm. from each other.

The complete motor car weighs 9.95 tons without passengers, the share of the electrical equipment being 3.7 tons.

Only a temporary car depot has yet been built.

Windmills for Lightships, etc.

The Canadian exploring steamer "Arctic" (Captain Bernier), which has made an extended voyage North poleward, is provided with a novel electric light installation. Since fuel cannot be obtained for the generation of steam, and as the ship will have to spend many months in darkness, it was decided to install an air-compressor plant which is being operated by a windmill. The compressed air is then used to drive the generators, which in turn furnishes current for charging the storage batteries used for lighting the vessel.

It would seem that windmills might similarly be utilized on board of lightships and alongside of lighthouses, for generating electricity for illuminating purposes and for the signal lights, in connection with electric storage batteries.

On Nansen's ship "Fram," there was a windmill electric set installed to give power during her Arctic voyage, and a similar set was placed on the ship

"Discovery" during her Antarctic exploring expedition, both of which worked admirably.—"American Shipbuilder."

MUCH LEGAL ADO ABOUT A TINY PIECE OF WIRE.

(From the New York Times November 19.)

Of all the patent lawsuits which have been waged in this country, perhaps none was ever more remarkable than that which came to a halt with the decision of Circuit Judge Hoyt H. Wheeler a few days ago. It was the case of the "Fessenden liquid barretter." The world heard merely that Judge Wheeler had decided in favor of Mr. Fessenden—only a few persons knew what days and nights of toil had been spent on account of a little wire that weighs a minute fraction of a grain and can hardly be seen without a microscope.

There are four volumes of the testimony taken by Commissioner John A. Shields. They weigh 35 pounds. The little wire which is responsible for all this bulk of evidence can be found with difficulty when it rests in the palm of one's hand.

Eminent patent lawyers were employed by the two contestants, Reginald A. Fessenden and the De Forest Wireless Telegraph Company. Besides the attorneys themselves—and there were more of them than are usually to be found in a sensational murder case—there were scores of unseen but hard-working assistants at work for months, busy delving into foreign lore devoted to inventions; there were translators to turn the French or German references into English, and there were experts drawing big fees to give their testimony.

The case has been going on for nearly two years, and it may be that the end is not yet. The De Forest attorneys still have a certain time in which to enter an appeal.

Mr. Fessenden invented his device in 1901. The scene of his labors was a lonely little island named Manteo, on the eastern coast of North Carolina. He continued his investigations at Old Point Comfort, Va. F. K. Vreeland, who worked with him in his experiments, figured in the litigation as a rival claimant to the invention. The court decided that Vreeland had no claim.

Whatever the merits of the case were or were not, Fessenden contended that the De Forest Companies were guilty of an infringement of his patent, and he brought an injunction suit in January, 1904. The complainant's proof covered 77 printed pages—and that was only a far-distant warning of what was to come later. Every day the case seemed to grow more complicated. The attorneys for both sides introduced as evidence technical records which might have driven the Judge to distraction had he not had long years of experience in the study of technical questions involved in patent cases.

To the man who is not familiar with wireless telegraphy the whole affair is very puzzling. The end of the little platinum wire, forming one of two electrodes, is immersed in a liquid. A continuous current passes through the liquid gap between the electrodes. The manipulation of a telegraph key hundreds of miles away causes variations in this current, and these variations, transmitted to a telephone, produce sounds corresponding to the letters of the telegraphic alphabet.

The number of minor claims and counter-claims in the case was so great that it would take a long time to catalogue them. At any rate, Judge Wheeler granted a permanent injunction restraining the De Forest Companies from using the device. If it is appealed, the case will go to the Court of Appeals of the Second Circuit.

The attorneys spent so much time and toil on the case that they got to carrying around microscopes in their pockets. These microscopes had to be brought into frequent use by both counsel and Judge. Even ordinarily patent lawyers have to know a great deal of electricity, mechanics, and other such scientific subjects, but in this case there was unusual need for thorough technical knowledge on the part of both lawyers and Judge.

The money spent by the contestants amounted to many thousands of dollars. The experts' fees alone would be nearly enough to float a corporation, and nobody knows just how much went to the lawyers, the referees and others concerned in the case.

Utilization of Victoria Falls.

The London "Times" announces that according to Reuter's Agency, the question of utilizing the Victoria Falls for the generation of electrical energy and its transmission to the Witwatersrand is receiving close attention at the hands of the African Concessions Syndicate. American and Continental engineers are agreed that such a project could be made commercially successful, especially as the climate is most favorable to the scheme, being extremely dry, whilst there is no ice in the rivers to interfere with the working of the turbines, and no snow to break down the transmission lines. It is estimated that in the dryest season yet experienced 500,000 hp. could have been developed The available head of water is about 330 feet, but a head of 1,000 feet could be obtained by engineering works of a comparatively light type. This head of water would produce 1,000,000 hp. At present, according to "Electrician," London, $15,000,000 is spent annually on power on the Rand.

New Hydraulic Electrical Stations.

Two new hydraulic electrical stations are to be built in Lyons, France. In one a 200 feet head in the Romanche River will afford energy for 10,000 hp., which will be transmitted as three-phase current over a line 90 miles long. The other plant, which will be located at Moutiers, will supply 5,000 hp. direct current at a pressure of 57,000 volts, and the current will be carried 110 miles over two overhead bare copper wires. Where it enters the city the conductors will be placed underground in well-armored cables. The current will be transformed to a lower voltage for commercial use by five motor generators. This is the first instance in which direct current of such a high pressure has been used in this manner, and also the first instance in which direct current at any pressure has been transmitted to any such distance.

Incandescent Lamps and Fires.

The extended use of electricity in mines gives rise to the belief that the dangers thereof are increased owing to the possibility of explosions caused by the heat from the lamp igniting the coal dust. This was demonstrated by a fire which took place at one of the collieries in the North of England some time ago. Investigations were then carried on by Mr. Hall, inspector of mines, who in a report states that in one case where a 16-cp. lamp was slightly covered with coal dust the temperature rose to 370 degs. F. in 10 minutes, and that in another case the lamp exploded at 450 degs. F. in four minutes, while a temperature as high as 650 degs. was registered in a third case. Mr. Hall remarks that after the coal dust has been raised to a certain temperature, spontaneous combustion commences.

Committee on Rates and Costs.

President Blood of the National Electric Light Association has reappointed the Committee on Rates and Costs which made report to the Denver convention. The committee consists of Messrs. Chas. L. Edgar, chairman; Louis A. Ferguson, Samuel Scovil, Frank W. Frueauff, P. G. Gossler and R. S. Hale.

Meeting of the American Society of Mechanical Engineers.

The 52d meeting of the American Society of Mechanical Engineers will be held in New York City during the first week in December. The headquarters will be at the Edison Auditorium, 44 West 27th street, the two upper floors being used.

The opening session, at which President John R. Freeman will present the annual address, will be held on Tuesday evening, December 5. The second or business session will be held Wednesday morning in the main saloon of the steamship "Amerika" at the docks of the Hamburg-American Line at Hoboken, N. J. Following this session a special train will take those desiring to make the excursion to the new Worthington Hydraulic Works at Harrison, N. J.

Wednesday evening there will be an illustrated lecture at the Edison Auditorium by Prof. R. W. Wood, of Johns Hopkins University, on "Photography of Invisible Phenomena."

The third session will be on Thursday morning, and besides the presentation of professional papers there will be a discussion on the subject of "Bearings." Thursday afternoon there will be a reception at the New York School of Automobile Engineers, 146 West 56th street.

The usual reception at Sherry's will occur on Thursday evening. The closing session will be held on Friday morning and will be devoted to the presentation of professional papers.

New York Electrical Society.

The 254th meeting of the Society will be held at 19 West 44th this (Wednesday) evening at 8 o'clock. Mr. O. S. Lyford, Jr., will lecture on "The Electrification of the Long Island Railroad."

Ohio Engineers' Meeting.

The eleventh annual meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers, held at Canton, November 17 and 18, was largely attended and a number of important papers were read and discussed. The delegates inspected the engineering plants in Salem and Alliance.

Telegraph Companies Not Liable.

Judge Sanborn, of the United States Circuit Court of Appeals, in three decisions handed down last week at St. Paul, Minn., holds that a telegraph company is obliged to use only ordinary care in determining the identity of senders of messages, and that losses sustained by persons whose names are improperly used are not to be held against the telegraph company. One suit was against the Western Union Telegraph Company to recover damages caused by the delivery of an unauthorized message alleged to have been signed by an Iowa bank guaranteeing payment of a draft for $8,972. The other two cases, also from Iowa, were similar.

Big Street Car System Sold to a Steam Railroad Company.

The United Traction Company of Albany, N. Y., controlling the street car system of Albany, Troy, Rensselaer and Cohoes, has been sold to Delaware & Hudson interests.

The sale of the property was announced after the meeting on Saturday last of the directors of the company as a result of two years' negotiations. Anthony N. Brady represented the stockholders of the company.

A circular issued Saturday night announces that all the directors have agreed to sell holdings, and that the sale is to be made at $150 a share, which price is available to all stockholders who deposit their stock before November 28 with the National Commercial Bank of Albany. The price is conditioned upon the surrender of at least 51 per cent. of the entire outstanding capital stock of the company before that date.

The price of $150 a share represents a total purchase cost of $7,500,000 for the stock of the United Traction Company.

Prof. J. L. Morris Dead.

Prof. John L. Morris died last Saturday night at Ithaca, N. Y., aged 73. Until he retired last year Prof. Morris had been at the head of the Mechanical Arts Department of Sibley College since 1868.

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until December 5 for furnishing Eastern Navy Yards with the following electrical material: Schedule 238, incandescent lamps; schedule 239, arc lamps; schedule 241, indicating fuses. Blank proposals can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington.

Captain B.B. Buck, constructing quartermaster at Fort McPherson, Ga., is inviting sealed proposals until December 1 for furnishing and installing electric light fixtures and making service connections between secondary lines and main line switches at Fort McPherson.

Sealed proposals are being invited until December 8 for furnishing the San Francisco depot of the Quartermaster's Department with a quantity of incandescent lamps. Detailed information will be furnished upon application to Major C. A. Devol, depot quartermaster at San Francisco, Cal.

ELECTRICAL PATENT RECORD

LETTERS PATENT ISSUED NOV. 14, 1905.

Electric Railways and Appliances.

804,297-298. Safety and Automatic Crossing System for Railways. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Leon F. Moss, same place. Filed May 15 and June 1, 1905.

804,371. Electromagnetic Wheel. Hugh Behan, Seattle, Wash. Filed Jan 6, 1905.

804,587. Car-Fender. Stefan Ebenschweller, Allegheny, Pa. Filed Aug. 3, 1905.

804,648. Trolley. Michael Baker, Chicago, Ill. Filed Aug. 31, 1904.

804,745. Electrically-Controlled Fluid-Pressure Railway-Brake. John S Lockwood, Kansas City, Mo. Filed Feb. 5, 1904. Renewed March 24, 1905.

804,763. Process of Electrically Welding Rails. Carl Pahde, Breslau, Germany. Filed July 11, 1905.

804,790. Car Fender. August J. Berg, Chicago, Ill. Filed July 12, 1905.

Electrical Machinery and Apparatus.

804,344. Electrically Switching Apparatus. Walter J. Richards, Milwaukee, Wis. Filed Nov. 4. 1904.

804,355. Dynamo-Electric Machinery. William L. Waters, Milwaukee, Wis. Filed Dec. 5, 1904.

804,389. Electric-Circuit Closer. Alexander Dow, Detroit, Mich. Filed Jan. 22. 1904.

804,438. Transmission Mechanism. Charles G. Simonds, Schenectady, N.Y., assignor to the General Electric Company. Filed June 23, 1904.

804,440. Dynamo Electric Machine. Charles P. Steinmetz Schenectady, N. Y., assignor to the General Electric Company. Filed April 22, 1904.

804 595. Electrical Controller. Nathan K. Garhart, Indianapolis, Ind., assignor to the Garhart Dental Manufacturing Company, same place. Filed May 25, 1905.

804,628 Electrical Generator. Morris Schwartz, New York City, assignor, by mesne assignments, to the New York Electrical Generator Company. Filed March 7, 1905.

804,636. Electric Snap-Switch. George B. Thomas, Bridgeport, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed Nov. 3, 1904.

804,783. Circuit-Controller for Explosive-Engines. Richard Varley, Englewood, N. J., assignor, by mesne assignments, to the Autocoil Company. Filed Oct. 31, 1904.

Telephones and Telephone Apparatus

804,256. Signal for Telephone-Switchboards. Frank R. McBerty, Evanston, Ill., assignor to the Western Electric Company, Chicago, Ill. Filed July 11, 1902.

804,279-280. Transmitter. Anthony Van Wagenen, Sioux City, Ia., assignor, by mesne assignments, to the Clark Automatic Telephone Switchboard Company, Providence, R. I. Filed April 30 and May 4, 1896.

804,431. Telephone Instrument. Egbert A. Reynolds, New York City, assignor to the Iron Telephone Company, same place. Filed Aug 19, 1904.

804,742. Push-Button Switch Mechanism for Telephones. Burton L. Lawton, Meriden, Conn., assignor to the Connecticut Telephone & Electric Company, same place. Filed Dec. 5, 1904.

Miscellaneous.

804,291. Electrical Apparatus for Producing Ozone. Albert C. Wood, Philadelphia, Pa. Filed Feb. 17, 1905.

804,365. Device for Preventing Contact in Telegraph Line-Wires. William L G. Appleby, Germantown, Md., assignor of one-half to Isaac N. Simpers, Germantown, Md. Filed Oct. 7. 1904.

804,603. Branch Block for Electric Wiring. Nathan B. Hoyt and James H. Martin, New Haven Conn., assignors to the Elm City Engineering Company, same place. Filed Nov. 14, 1904.

804,759. Electrical Heater. John A. Noble, San Francisco, Cal., assignor of one fourth to Edgar C. Gribble, one fourth to Alonzo C. Gribble and one-fourth to James Davis, San Francisco, Cal. Filed May 8, 1905.

THE TELEPHONE WORLD.

Telephone War in Prospect.

It is evident that a telephone war is on in Tecumseh, Neb. An Independent company is being organized among the business men, and the Bell company has long maintained an almost complete service in Johnson County, a large exchange being in force in Tecumseh. Much complaint has been made concerning the service given by the Bell company, the Commercial Club having been asked to take a hand in the matter. Relief was promised by the telephone company, but that did not head off a movement for an Independent company. Mr. Otto Wettstein, Jr., of La Porte City, Ia., has been in Tecumseh endeavoring to organize the new company and has met with sufficient encouragement to warrant the new enterprise.

A Network of Independent Lines.

The Stantonville, Tenn., Telephone Company is erecting poles for the purpose of extending its lines to Parsons with a view of putting in an exchange in that place. It will also extend its line to Camden. The various counties in that section are a perfect network of Independent telephone lines, and there are many private lines in operation. The farmer who is not in telephonic communication with his neighbors and with the nearest town is not up-to-date.

At the recent convention of the Texas Independent Telephone Association, held in Dallas, each of the 75 Independent companies having lines in Texas were represented at the meeting. The principal subjects discussed were the promotion and general interest of the Independent companies in the State, the matter of adjusting toll line rates, and the completion of the Independent telephone companies, clearing house. After the general business was over the directors who had been elected met to perfect the organization of the Independent Telephone clearing house, which is to be established in Dallas. The following officers of the clearing house were elected: President, Cecil L. Simpson, of Dallas; vice-president, E. P. Butler, of Gainesville; secretary and treasurer, E. W. Dunaway, of Paris. The directors decided upon Waco for the next place of meeting, at such time as the executive committee shall decide to call the members together.

An Independent telephone company has been organized to install a complete system of telephones in New Wilmington, Pa. The company is being organized in opposition to the Bell system. The required capital will be furnished by local capitalists.

H. W. Trimble, foreman of the Nebraska Telephone Company, is now engaged in Blair, on the extensive repairs being made by the company. The new system is expected to be in full operation and all work completed by the first of the year. All the old 'phones are to be removed and will be replaced by up-to-date ones.

The Nebraska Telephone Company is building a farmers' line near Pickrell.

A telephone strike seems to threaten the Mutual Telephone Company of Des Moines, Ia.

Victory for Home Telephone Company.

Decisive victory for the Home Telephone Company in its struggle with the Cumberland Telephone Company was the result of a vote of the Springfield, Tenn., city council, when that body decided unanimously not to interfere with the franchise granted to the Home Company about one year ago to do business in Springfield.

For some time petitions have been circulated asking the city council to declare the franchise of the Home Company ferfeited because of failure to take advantage of the rights granted within a reasonable time. The petitions also declared two companies unnecessary, and that another system would cause many inconveniences and expenses to the patrons of the telephone. Such petitions were circulated, it is alleged, in behalf of the Cumberland Company.

The city council, by its action, held that a reasonable time in which to begin building has not expired, and the Home Company may proceed to comply with the terms with the support of the town authorities. The company now has its poles, preparatory to erecting lines, and will begin work at once. E. L. Barber and A. L. Tetu, the men at the head of the Nashville Home Telephone Company, are behind the company and the opening of an office will give Springfield Independent telephone communication with a number of other places where allied Independent companies have lines.

The action of the city council in opposing the attempt to obstruct the Home Company in efforts to come into Springfield meets with general approval.

The claim is made that the Cumberland Telephone Company has never been granted a franchise in Springfield, and has no right to run its lines over the streets.

Directors' Meeting Postponed.

The meeting of the directors of the United States Independent Telephone Company, scheduled to be held in Rochester, N. Y., last week, has been postponed until November 23, when it is expected all the directors of the new corporation will be present.

The American Telephone & Telegraph Company's October net output of instruments was 133,199, against 62,988 one year ago, and from January 1 the net output was 976,852, against 564,672 in the same period last year. The total number of instruments outstanding is 5,457,416, compared with 4,344,189 one year ago.

The Delmarvia Telephone Company of Wilmington, Del., lately destroyed about 1,000 of its old instruments.

The Farmers & Merchants' Telephone Company of Beaver Springs, Pa., has been incorporated with a capital stock of $6,000.

C. E. Stinson, of the Toledo, O., Home Telephone Company has been appointed consulting engineer for the Indiana long distance and the Indianapolis city plant.

The Cumberland Telephone Company is erecting a building in White Bluffs, Tenn.

Telephone Bonds.

The Independence, Mo., Home Telephone Company through its president, Theodore Gary, of Macon, Mo., has filed a mortgage deed of trust in Independence in favor of the Pioneer Trust Company of Kansas City to secure $150,000 in bonds recently authorized. The bonds are to run for 20 years at 5 per cent. Of the amount of money to be raised by the sale of the bonds, $50,000 is to be used in paying for the plant as it now is, $25,000 in immediate betterments, and $75,000 as a reserve for future improvements.

Farmers to Have Telephones.

Articles of organization have been filed for the Brown County, Wis., Telephone Company with a capital stock of $10,000. The company has been incorporated by three Green Bay men—State Senator Henry F. Hagemeister, Charles A. Straubel and F. J. B. Duchateau—for the purpose of building and operating a toll and local telephone system between Green Bay and the town of New Denmark. It is the intention of the corporators to have the company's line ultimately extended to Manitowoc, and also in other directions.

The private telephone between Green Bay and Senator Hagemeister's stock farm in the town of Bellevue, it is announced, will be used as a nucleus for the first span of the system.

The intention of the promoters is to have work started early next spring.

The controlling interest in the Monrovia, Cal., Telephone & Telegraph Company, which owns the Home Telephone franchise in Monrovia, has been taken over by Dr. West Hughes, of Los Angeles. The office of president is held by Dr. Hughes, J. M. Baldwin has been elected vice-president and manager, and F. N. Hawes, of the American National Bank, secretary-treasurer. These, with F. J. Cornes, are the board of directors. An improved system is promised.

It is stated that the total number of Independent telephones in Indiana at the present time is about 175,000. This enormous development has been achieved within six years. There have been fewer failures among Independent companies than in any other class of business, and no company has been in the hands of a receiver.

The Bradford, N. Y., Telephone Company has been incorporated to operate between Bath, Savona and Bradford. The capital of the company is $2,000 and T. W. Chase, of Bath; F. S. Owenshire, of Urbana, and Edgar Sanford, of Bradford, are the directors.

Announcement has been made of the sale to the Home Telephone Company of Kansas City, Kan., of a controlling in the Ottawa Telephone Company. The new concern takes control of the plant December 1.

The Home Telephone Construction Company of Los Angeles, Cal., is a newly organized concern. The directors are as follows; Carl L. Doran, C. G. Andrews, Philo Jones, M. Andrews and G. Doran, of Los Angeles. Its capital stock is $500,000.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Ashburn, Ga.—This town is considering the installation of an electric light plant and waterworks, and preliminary surveys have been made by J. B. McCrary, of Senoia.

Astoria, Ore.—W. W. Whipple has secured a franchise to construct an electric light and gas plant, also a telephone system.

Beaumont, Tex.—The Beaumont Saw Mill Company is arranging for the installation of a complete electric light plant.

Bluff City, Tenn.—An electric light company has been organized here with J. D. Haun, president; W. E. Wolfe, vice-president, and J. H. Bachman secretary and treasurer.

Buena Vista, Ga.—An election will be held December 11 for issuing bonds for an electric light plant. There is no doubt but that the bonds will be issued, as the whole town is very enthusiastic over having an electric light and waterworks system.

Chetek, Wis.—The citizens are desirous of having an electric light plant.

Crawfordsville, Ind.--J. F. Davies, of Toledo, O., has secured the contract for repairing the city electric light plant.

Fort Payne, Ala.—The Alabama Cooperage Company of this place has made application to the council for an electric light franchise.

Fort Smith, Ark.—John W. Howell, Joseph G. Branch and others of St. Louis, Mo., have applied for a franchise to construct and operate an electric light plant.

Galva, Ill.—Dr. B. S. Peck, Randolph Boyd and others have petitioned the village board for a franchise to establish an electric light plant.

Grand Forks, N. D.—Edward A. Healy, of Red Lake Falls, has a plan to supply electric light for this city, and has been here talking over the venture to the local business men. His plan is to utilize the power of Thief River Falls to generate current, which if extended here will furnish cheap light.

Grand Island, Neb.—The Grand Island Electric Company has been incorporated with a capital stock of $60,000 by Arthur F. Vila, G. H. Payne, Irving F. Baxter and others.

Huntsville, Ala.—A number of local citizens are agitating the question of the city making a bond issue sufficient to erect and equip an electric light plant.

Jonesboro, Ind.—The Trowbridge Company of Chicago has purchased the Jonesboro light and water plant, and will make extensive improvements, one of which will be a 24 hour service.

La Barca, Mex.—Francisco Castallanos proposes to establish an electric light and power plant here.

Loveland, O.—The Loveland Citizens' Electric Company has decided to issue $50,000 bonds to be used for extension of the plant.

Minneapolis, Minn.—At the special election held here last week, the proposition to issue $35,000 bonds for the building of a municipal electric lighting plant was carried by a large vote.

Mineral, Kan.—The Sun's Rays Electrical Company has asked for a franchise to install an electric light plant here.

Morganton, N. C.—An electric light and power plant will be erected here by the Morganton Furniture Company, lately incorporated with a capital stock of $125,000.

Norfolk, Va.—In order to make further extensions in its plant for the purpose of increasing its electric lighting facilities, the Norfolk Railway & Light Company contemplates shortly an outlay of $100,000.

Osborne, Kan.—Frank A. Higley, of Cummings, has asked the city council for an electric light franchise, and proposes to put in a lighting plant here if given a free site for the power house.

Sacramento, Cal.—E. J. Carragher is clerk of a committee appointed to find ways and means of establishing a municipal electric lighting plant.

Scottsburg, Ind.—The city council has granted a franchise to James Smith for an electric light plant.

South Hanson, Mass.—A new company will soon be incorporated in this town, known as the Hanson Gas & Electric Company, with W. E. Damon as president.

Terre Haute, Ind.—This city is to establish its own electric lighting plant.

Texarkana, Tex.—S. B. Whiteside and G. West have applied for a franchise for an electric light plant here.

Toledo, O.—The citizens have voted in favor of the issuance of bonds for the purpose of building a municipal electric lighting plant.

Wesson, Miss.—The city council is negotiating for the purchase of the electric lighting plant, now owned by a private company.

White Bluffs, Tenn.—There is talk of waterworks and an electric light plant for this place.

Williamsburg, Ky.—Gleaves & Company of Lynchburg, Va., propose to construct and own waterworks and an electric light plant here to cost about $45,000. J. A. Gilman is the engineer.

STREET RAILWAYS.

Canal Dover, O.—Engineers are at work surveying the land between here and Alliance, for the purpose of estimating the cost of building an electric railway between the two cities via Bayard, Magnolia and Bolivar.

Cincinnati, O.—The Cincinnati Belt Railroad Company, which proposes to build an electric railway to Garry, both freight and passenger, has been incorporated with a capital stock of $18,000 at Columbus, by Jacob Joseph, P. Peurrong, O. C. Evans, K. F. Beckhardt and V. Q. Price.

Ephrata, Pa.—The citizens have started a project for the construction of a new trolley line from here to Lincoln, with the expectation of subsequently extending it to Lebanon.

Frederick, Md.—The Dodge surveying corps, employed by the parties who propose to build another trolley line connecting this city and Hagerstown, is still at work.

Fort Wayne, Ind.—An electric road from this city to South Bend, a distance of 80 miles, passing through a prosperous farming country with a population of 1,752 to the mile, connecting two of the best cities of this State, and opening a territory which is now reached directly only by wagon roads, is what is promised by the Fort Wayne-South Bend Air Line Traction Company.

Hatboro, Pa.—The right of way for the proposed trolley route from Newtown to this place has been secured and officials say the work of construction will begin early next spring.

Morgantown, W. Va.—Work will begin on a trolley line April 1, to connect this city with Fairmont. Senator Elkins and Joseph H. McDermott are the promoters.

Oakland, Cal.—Articles of incorporation of an electric railroad to run from Marysville to Nevada City, and thence to Auburn, were lately filed here under the name of the Midland Railroad Company.

Petersburg, Ind.—The city council has granted a franchise to the West Baden, Louisville & Vincennes Electric Road, giving it the right to enter this city upon any street except the main business thoroughfare.

Sherman, Tex.—Local officials of the company to construct and operate the proposed electric line from this city to Gainesville announce that the contract has been awarded, and the work will be commenced soon.

POWER PLANTS.

Birdsboro, Pa.—The Birdsboro Electric Light & Power Company will erect a power plant along the Schuylkill road.

City of Mexico, Mex.—V. Martinez, of this city, will build an electric plant for the transmission of power at a place between the States of Morelos and Guerrero.

Detroit, Mich.—The big Commonwealth Power Company has nearly completed negotiations for purchasing the water power rights of the Huron River above Ann Arbor. The probable purchase price is said to be close to $150,000.

BIDS WANTED.

Boise City, Ida.—W. N. Donaldson, of the Boise Valley Electric Railroad Company, gives information that the company is in shape to proceed with the construction of the line to Caldwell. Bids are invited for the equipment of 30 miles more of road. The conditions of the call for bids require that the successful bidder shall be ready to begin shipments within 30 days.

New York City.—Sealed bids or estimates will be received by C. B. J. Snyder, superintendent of School Buildings, at the Department of Education, corner of Park avenue and 59th street until 11 o'clock A.M. on November 27. No. 1 for installing fire alarm telegraph system in public schools 2, 4, 5, 7, 8, 9, 10, 12, 13, 15, 30, 32, 39, 40, 47 and 111, Borough of Brooklyn. No. 2 for installing electric equipment in new public school 149, on the south side of Sutter avenue, between Wyona and Vermont streets, Borough of Brooklyn. On contracts Nos. 1 and 2 the bids will be compared and the contract awarded in a lump sum to the lowest bidder on each contract. Blank forms may be obtained and the plans and drawings may be seen at the office of the superintendent at Estimating Room, Hall of the Board of Education, Park avenue and 59th street, Borough of Manhattan; also at branch offices, No. 131 Livingston street, Borough of Brooklyn.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 16⅝@16¾c.; Lake 16⅝@16¾c.; casting, 16⅜@16½c.

The annual meeting of the stockholders of the West End Street Railway Company of Boston will be held November 28.

The Interborough Rapid Transit Company of New York is increasing the number of its employes. About 500 new men are required.

The Kings County (Brooklyn) Electric Light & Power Company's quarterly dividend of 2 per cent. will be payable December 1.

The Electric Company of America (Philadelphia) will shortly issue about $500,000 of new stock. This will be offered to stockholders at par.

General Manager Stebbens, of the Appleyard electric lines in Ohio, announces that the properties will be offered for sale within the next 60 days.

The Philadelphia Electric Company has declared the regular semi-annual dividend of 2½ per cent., payable December 15 to holders of record November 24.

In the first 17 days of November the Amalgamated Copper Company is said to have sold 48,000,000 pounds of copper, deliverable as far ahead as February.

The Washington (D. C.) Railway & Electric Company has declared the regular semi-annual dividend of 2½ per cent. on its preferred stock, payable December 1.

The president of the Chicago & Milwaukee Electric Railway Company has closed a deal for the purchase of the franchise of the Kenosha (Wis.) Electric Railway. The consideration was $350,000.

In spite of the continuous decline of Metropolitan Street Railway and Metropolitan Securities, large holders have maintained an air of confidence which, as a certain banker familiar with the property put it, conveys the impression that "they have something up their sleeves."

The recent advance in Brooklyn Rapid Transit and the buying of the stock by Philadelphia houses was considered as partial corroboration of the designs of the Pennsylvania Railroad "inside crowd" on Brooklyn Rapid Transit. Insiders of the latter talk bullish, but give no very active assistance to the bull movement.

Comptroller Grout announces that he will take steps to prevent the United States Independent Telephone Company from doing a general telephone business in New York under the franchise of the old Mercantile Electric Company. The New York Independent Telephone Company acquired control of the Mercantile Electric Company recently.

The voting trust of the Lake Shore Electric Company was voluntarily dissolved on Saturday at Cleveland, O., the properties subserved by it having been rehabilitated to such a degree that its services were no longer necessary. The trust was constituted at the outset of the Everett-Moore troubles in 1902. The property now reverts unhampered to its owners. The line extends from Cleveland to Toledo.

Preferred stockholders of the Bullock Electric Company of Cincinnati, which is controlled by the Allis-Chalmers Company, may exchange dollar for dollar until December 12 for preferred stock of the Bullock Electric Manufacturing Company. At present the stock is guaranteed 6 per cent. for 23 years. The new stock is guaranteed at 6 per cent. for unlimited time, is cumulative and is preferred as to assets and liquidations.

EDITORIAL NOTES.

The Transformation of Central Stations.

Since the question first arose as to whether electricity would ever become a force of commercial use tremendous strides have been made in the direction of making it an essential element of everyday life. But it is not alone this widespread application of electricity to lighting and power which demands attention. It is a matter of more interest to examine into the character, and the changes in character, which have occurred in the *ensemble* of those sources of electrical energy commonly called central stations. This change in *ensemble* has been noted by modern-minded engineers as a proof of the elasticity of present day practice. It is a striking evidence of the degree to which changes are instituted on the basis of a well founded, though partially crystallized, scientific principle. To be more explicit, it may be stated that a rapid transformation is taking place in the design of the operating mechanism of central stations. As a central station is best designated as an institution in which electricity is generated for direct distribution and consumption, it may not be difficult to understand how changes occur in the class of machines housed under such a roof. These changes are very marked at certain intervals, indicating transformations through definite periods. Formerly the change was one indicating a strong tendency to use large multipolar units instead of a variety of small two-pole machines. Of necessity this expansion led to the abolition of the use of small high speed engine units, and the heavier build of slow moving engines of the marine type took their place. Thus the station was gradually evolved from the first period of development, consisting of small bipolar dynamos belted to high-speed engines, into the second stage of growth, represented by a series of large slow-speed multipolar generators, direct connected to correspondingly heavy engine units. What can be called the third period of development, now regarded as the most radical of its kind in the last half century? The answer to this interrogation is best found in the statement that the third stage of central station development and transformation is discovered in the introduction of the turbine.

It might be asked, how can the introduction of the turbine affect the central station so markedly? Or in what respect are such advantages gained that the substitution of one type of steam consuming apparatus for another is to be hailed with approbation? Only a purely commercial reply can be made to this inquiry. It is decidedly cheaper to install and employ turbines than engines. The lowering of the expense is found in the more limited rate of depreciation; in the greater economy of operation and in the reduced consumption of oil. The greater ease of coupling is not as great or as important an item as the reduction in floor area. It is far better to produce continuous rotation by steam or any other power if possible than a series of disconnected and reversing impulses. The reciprocating engine is thus debarred by natural law from standing on the same plane of mechanical perfection as the turbine. As there is in this, as in the generator, only rotation to consider, it is not susceptible to the same wear and tear as a mass of linked mechanism needing constant attention and careful lubrication. This therefore is the point of greatest interest—the saving in labor for care and attention. The explanation of the transformation of central stations into turbine-driven plants is thus found; in one instance emphatically, but in all other instances as an economical measure as well. If floor space can be occupied to better advantage then more generating units can be installed. The logic of this, the general use of the turbine, seems to be not only a saving on all sides, but what is equally important, an ability to utilize the space of the central station to such advantage that a greater income can be secured from it. Viewed from this standpoint, it is evident that the three steps of progress as enumerated are as beneficial financially as scientifically, and certainly as advantageous commercially as practically. As an additional fact, it may be stated that, according to the latest statistics, more than 900,000 hp. in turbines are now in use, largely in central stations.

* * *

Radium and Lead. Radium and lead are supposed to be closely related to each other, according to the surmises of one or more of our distinguished electro-chemists. The emanations of radium are supposed at present to pass through evolutionary changes. In one instance one of the so-called elementary forms is produced; in another instance, another of these products. Radium as now understood produces alpha, beta and gamma phenomena, as they are called. But it has been noted that the geological conditions under which uranium ore is found, and the drift of the present theories regarding it, all point in the same direction. Molecules represent a heterogeneous assemblage of atoms. The atoms represent planetary systems in which occasional disruptions take place. When such events occur the process spoken of, the transmutative process, will give rise to the gas helium. The breaking up, as it is called, of the molecule and atom is a creative event, in that new elements are originated. It is presumed that the so-called fixed elements are the results of a past process of this kind, now however slowed up. From a simple substance presumably the complex has been born. From radium, on this basis, lead owes its origin, if the hints and deductions of science are to have any weight in the consideration of such vast problems as the cause of matter as we know it.

* * *

An Improvement in Wiring. The risks of fire and injury to wires have been receiving attention from many engineers interested in the development of safe electric wiring. The use of moulding, iron pipe and insulators for the protection of current-carrying wires, has at times been subjected to the criticism that, although safe, they represent only a form of protection that is not part of the wire itself. It has been suggested by some English specialists that great improvements would result if wires were lead-encased and made into twin conductors. The suggestion was based upon the idea that a pair of lead-covered wires could be readily installed. Where they are to be buried in plaster they could be quickly attached to the wooden joists generally found in walls or to the mortar foundation otherwise present. The burying of them in plaster could not affect their strength of position nor increase the fire risk to any marked extent. Such are the arguments advanced in favor of twin conductor lead-covered wires by our English friends; and it must be admitted that they are sound enough. But it is hardly necessary to remind them of the differences between our skyscrapers and their low office buildings. Feeders or risers supplying the upper floors, and in fact all floors, would occupy so great a space that the mere "burying in plaster idea" would not do. Pipe ducts are very convenient additions, not only because pipes are used but for the better reason that in this manner all conductors are accessible. It is a question whether it would ever pay to bury conductors, even such as are used in rooms, permanently in plaster.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The electrical exhibition to be held at Madison Square Garden in this city for two weeks, beginning December 12, will be formally opened by President Roosevelt, who, by the pressure of a button in the White House, will set in motion the machinery of the exhibition.

According to a report recently issued by one of this country's representatives in the Far East the opening out of Japan is likely to be followed by rapid development in China. This vast empire, with its enormous resources, kept in the background by the ancient superstitions and indolence of its inhabitants, cannot remain permanently invulnerable to the wave of regeneration which is sweeping over that section of the globe, and soon the country will be ready for the exploits of the electrician.

Several railway officials went on a short trip out of Philadelphia last Thursday to test a new electrical locomotive designed to replace the ordinary steam locomotive, especially on branches and spur lines. The new engine, which is capable of making 50 miles an hour, and which is of a peculiar type, is the invention of Lars Nelsen.

The Cunard Steamship Company, says the "Electrical Engineer," London, has already five of its North Atlantic steamers fitted with the submarine signaling apparatus, and it is understood that the "Carmania," the largest turbine-driven steamer in the world, and the first to run between Europe and the United States, will also be possessed of an equipment. Trials have been made on board the German steamer "Deutschland," from which the bell at the Outer Weser lightship was located at a distance of five nautical miles, while the noise made by the propeller of a large passing steamer was distinctly heard at a distance of 1½ miles, though the "Deutschland" was steaming 19 knots.

Porto Rico is now connected with Key West, Fla., by wireless telegraphy.

The pole line insulators on high tension transmission lines in California have to be protected, according to the "Canadian Electrical News." The natural deposition of moisture upon them in fogs, or of dust in dry weather, is apt to cause short-circuits, resulting in burning, and often destroying the pole. This is now prevented by sheltering all insulators by Λ-shaped boxes or sheds.

Americans are to equip the city of Quito, Ecuador, S. A., with an electric light and power plant.

Considerable use is made in Germany of electromagnets for lifting and transporting iron castings, etc., in workshops, says the "Electrician," London. The form of magnet employed varies with the kind of material to be lifted. For lifting objects with an uneven surface, for instance, electromagnets are used, the poles of which are capable of a certain movement so as to adapt themselves to the uneven surface. For lifting material of a thickness of at least 2 inches, the best magnet in all respects is said to be the "pot" type of electromagnet. If the object to be carried is long and narrow, it is usual to arrange a number of electromagnets side by side in a common shell, and for transporting sheet metal the magnet is provided with a number of poles in a cluster.

GERMAN APPARATUS FOR PREPARING FILAMENTS.

BY FRANK C. PERKINS.

The accompanying illustration, Fig. 1 and drawing Fig. 2, shows the construction and arrangement, as well as the electrical connections of an interesting German electrical equipment for preparing carbon filaments for incandescent lamps. This apparatus is constructed at Berlin by Ganz & Goldschmidt, and consists of a contact ammeter as noted in Fig. 1, together with a rheostat noted in the illustration, also at d, in Fig. 2, together with a direct reading ohm-meter and magnetic contact devices. The filaments are placed in a receptacle f, and connected with the current, the contact ammeter a being placed in the circuit, and the carbonized filaments are subjected to heavy hydro-carbons.

As well known the thinnest portions of the filaments become incandescent first, the solid carbon being deposited on their surface, owing to the reduction of the gas. As soon as a uniform section is produced throughout its entire length, the section will increase during the incandescence at a uniform rate. The current from the battery b, noted in Fig. 2, actuates the relay c, and the circuit is automatically opened by the contact ammeter interrupting the working circuit at e, this action occurring with a given maximum current intensity, which is characteristic for each cross-section of the filament.

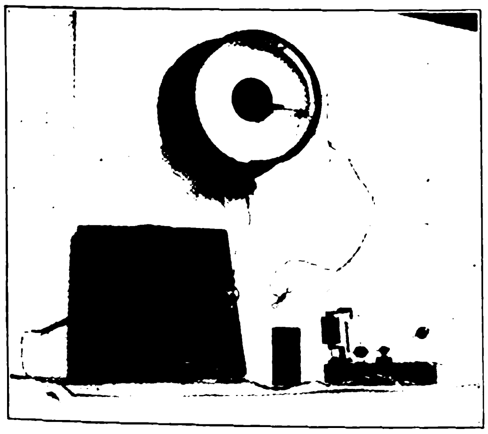

Fig. 1.

By adjusting the shunt resistance indicated in d, the sensitiveness of the apparatus may be varied for any desired thickness of filament, and it is stated that the diameter of the filament prepared by this apparatus will be accurate within 1 per cent. It is stated that this outfit is more suitable for preparing carbon filaments than the bridge process which is frequently employed, as it responds independently of the length of filament and lamp tension to a given cross-section of the filament and not to a given resistance of the filament, The rheostat is marked with indications, showing the current intensity at which the preparing current for the carbon filament is automatically interrupted, and it is stated that the apparatus is also divided into scale divisions, which give the diameters of the filaments, and by this means the outfit may be operated by attendants who are not particularly skilled in the art. The scale of the direct reading ohmmeter before mentioned is divided into diameters of filaments which makes it possible for the filaments which have been prepared to be checked as to their diameters one with another. It is claimed that even with an ohm-meter divided into ohms, sufficient accuracy is obained, and several hundred resistance measurements may be made each hour. This apparatus is of special interest to those engaged in the manufacture of incandescent lamps in the United States, showing as it does one of the unique German devices for preparing filaments.

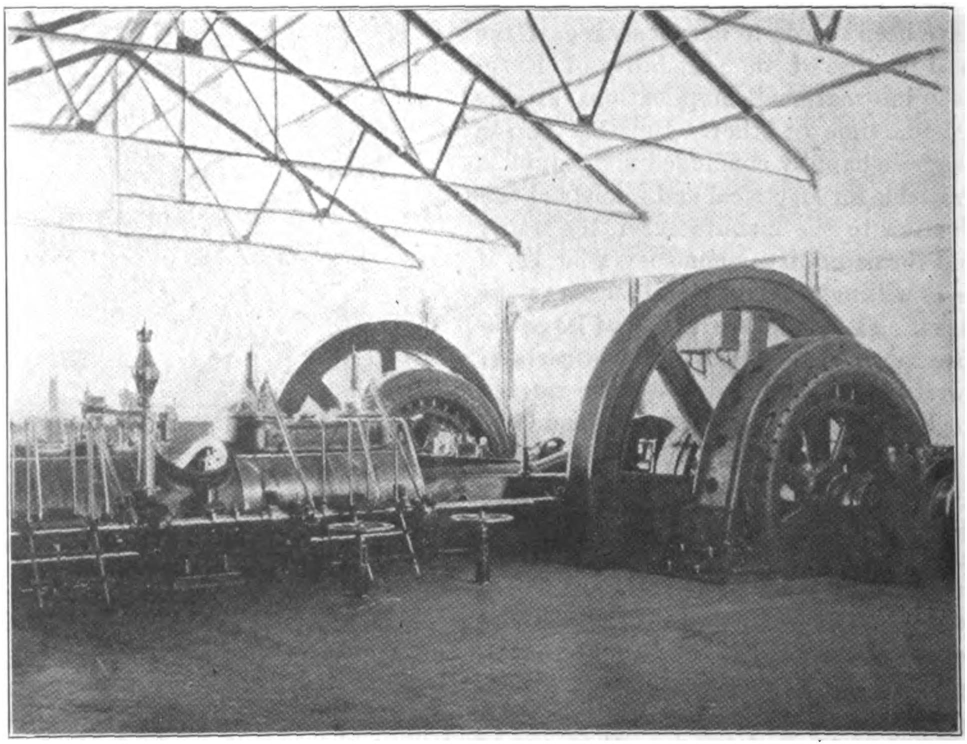
AN EGYPTIAN ELECTRIC RAILROAD.

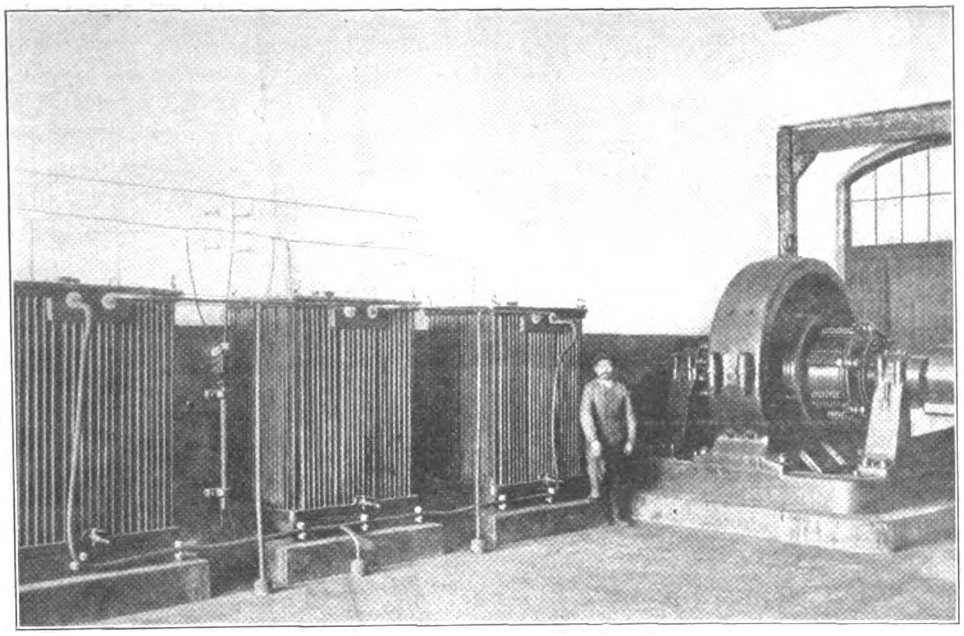
(From our London Correspondent.)

During the last decade electrical engineers, both European and American, have looked toward Egypt with a wondering business eye. On the part of none can it be said that there has ever been very great enthusiasm regarding the immedi-



Power House Alexandria Ramleh Railway.

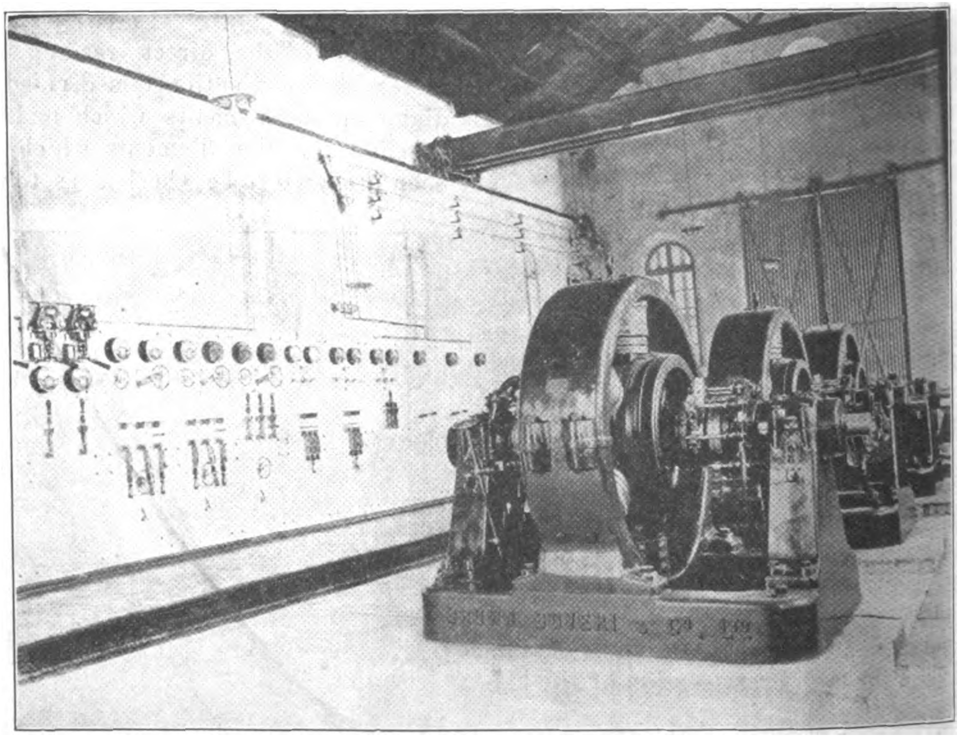
ate electrical trading possibilities. Many years ago a proposition by a leading English authority for the utilization of the great Nile Cataracts reached the Institution lecture stage, the cost of copper transmission lines for a long distance scheme and many like particulars being worked out according to the then known results of what then was regarded as long distance work. If we remember rightly, the Egyptian Government went so far as to have a report on the whole situation and future electrical transmission possibilities and their effect upon the general development of the land prepared by this same authority.



The 350 Kw. Converter and Transformers in Power Station.

This was in the days when there might have been reason to nervously regard the land because of the possibility of European international complications arising at some time or other. But that period has been happily concluded and Egypt is available for electrical and industrial cultivation to the manufacturer, the trader and the capitalist, whomsoever he be, if he is willing to lend his aid and bear the risks. That Egypt is a field of large future possibilities electrically is certain, but its immediate needs are being catered for by British, Swiss, American and German firms. It is only a short time ago that half-a-dozen of the important British makers of engines, dynamos, cables, etc., combined to jointly seek electrical business in Egypt.

Mention has been made of the proposal for the utilization of the Nile Cataracts, and with the more modern data that is now accumulating for expert application to that problem the accomplishment of this object for rendering vast lands, which are at present valueless, of considerable use and value, is almost in sight. Electric lighting and traction development are, however, taking place already in the more important towns, such as Port Said, Alexandria and Cairo. In some of these Belgian enterprise was responsible for the introduction of works and tramways, but control has now passed into Egyptian hands. The tramways of Alexandria are worked by the Alexandria & Ramleh Railway Company. The town lines were owned by the Societe Anonyme des Tramways de Alexandrie of Brussels, but these as well as the recently electrified connection between Alexandria and its eastern suburbs, are now both worked by the Alexandria & Ramleh Company.

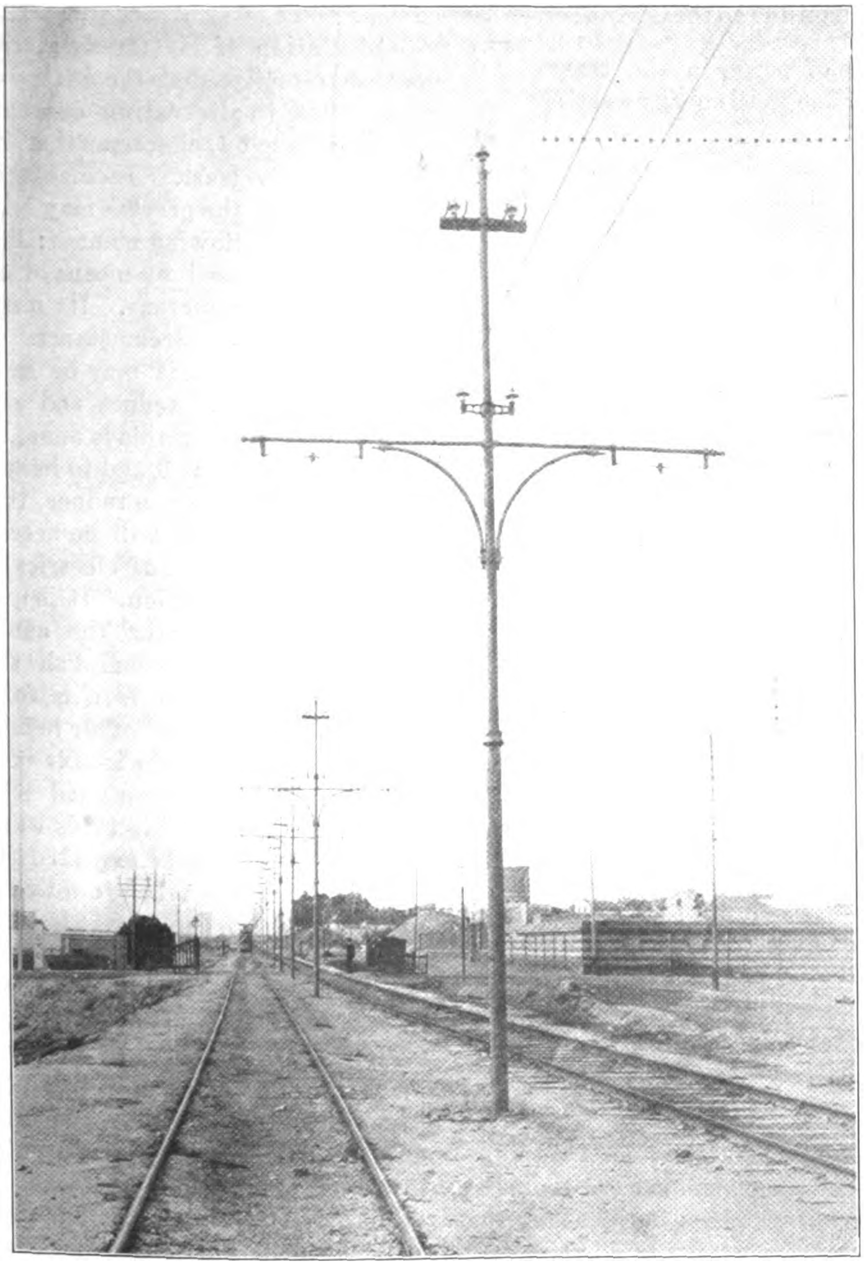


Bulkeley Sub-station.

In the accompanying illustrations are given some views of the Alexandria-Ramleh lines and their power equipment. Up to last year this line was operated by steam, but the continually increasing tourist traffic led the company to resolve upon some better method of locomotion, and a scheme was adopted which involved among other things the installation of two 600 kilowatt three-phase alternating current high tension generators of the revolving field type (speed 107 revolutions, pressure 6,500 volts, frequency 25 cycles per second) of Brown, Boveri & Co. of Baden. These have been erected at the Alexandria Company's central station, direct coupled to horizontal tandem steam engines by Tosi. There are ten Elephant type boilers (135 pounds per square inch) installed; they are hand-fired, use bituminous coal, and are equipped with Green's economizers and Worthington pumping plant. A transmission line has been erected connecting the central station to a sub-station near Bulkeley (half way between Alexandria and Ramleh). The three-phase high tension current is converted to low tension and then to continuous current by means of stationary and rotary transformers.

The magnet wheel of the alternators is not fixed on the shaft of the engine, but is connected to its fly-wheel by means of a flanged coupling. There are two 35 kw. continuous current machines for exciters. The switchboard is on the usual Brown-Boveri principle; two panels are for alternators, one for exciters and two for feeders. The high tension panels are provided with oil switches, and the feeder panels have overload circuit breakers for safeguarding the transmission line.

Current is led from the power station to the sub-station 10.5 km. away by two three-core cables. In order to avoid crossing the inhabited quarter with a high tension line two underground cables are laid for the first portion, and on the way to Ramleh connection is made with an ærial line. From this point the high tension feeders are carried to Bulkeley sub-station on the center poles of the system, which also carry the trolley brackets.



Overhead Three-phase 6,500 Volt Transmission Line.

A feature of this high tension line is the provision of grounding forks under each line wire upon both sides of each insulator, so that if a high voltage wire breaks it drops into the fork and is immediately grounded and rendered harmless.

The Bulkeley sub-station is situated in the center of Ramleh, about eight miles from the power plant, and it contains three three-phase transformer sets, each set consisting of three single-phase static transformers of 110 kw. connected up in delta and designed to reduce the tension from 6,500 to 350 volts. The transformers receive the current from the high tension bus-bars through three oil switches. The alternating current at 350 volts is led to three rotary converters which convert it into a 560-volt continuous current. Each converter is of 300 kw. capacity at 500 revs. per min. This arrangement dispenses with bus-bars for the low tension alternating current and greatly simplifies the wiring and manipulation of the board. The converters are started from the continuous current side, current for this purpose being generated by a 50 hp. asynchronous continuous current motor generating set. The rotary can also be brought up to synchronism by admitting the secondary current from the transformer direct on to the armature and closing the exciting circuit, as usual. Besides the shunt winding these converters are provided with two compound windings which can be put in series or in parallel, the object being to obtain, in conjunction with choking coils in the alternate current circuit, a tension variation from 500 volts at no load up to 525 volts at full load, with compound windings in series.

The four feeders from this sub-station are for four sections thus: Alexandria up to Bulkeley; Bulkeley down to Alexandria; Bulkeley to S. Stefano along the old track; from Bulkeley to S. Stefano along the new line.

Each first-class motor-car has a trailer for second-class passengers. They are of European double-deck type.

It ought to be added that at the central station a 350 kw. converter has also been installed to work in parallel with the continuous current machines for supplying the town tramway service; it also re-converts from continuous to alternating current when the small load on the sub-station renders it uneconomical to have the 600 kw. group working.

It is understood that the change over of this line to electric traction increased the traffic by some 33⅓ per cent. in a very few months.

LIGHT, HEAT AND POWER PRINCIPLES.—X.

BY NEWTON HARRISON, E. E.

Mutual and Self Induction.—Both inductions are caused by the interlinking of lines of force with the turns of wire. The transformer is peculiarly representative of a case where mutual induction occurs between the primary and secondary coils, and self induction in each coil individually. An illustration, showing the self-inductive relationship in any coil when current is introduced, to the current due to the impressed EMF., will serve to emphasize the true meaning of this phenomenon. It is not essentially different when an alternating current is introduced, except in so far as it represents more complications, because of the rise and fall to zero of the current in one direction, and its rise and fall to zero in the opposite direction. The influence op-

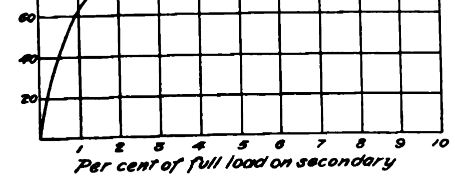
Action of a primary on a secondary coil.

erating is always reactive. By this is meant, that when the current attempts to grow in strength the reaction grows likewise. Whereas, on the other hand, when the current tends to decrease in strength, the reaction is reversed. It then strengthens the current as it tends to diminish, sustaining it, beyond its normal time, and causing the flash or kick to appear when the circuit is broken.

The entire process is due to the effect of a variation in the lines of force when the current is either increasing or diminishing. In a transformer the inductance is three-fold in the sense that both self and mutual inductance occur in the two coils as follows: 1st—Self-induction in the primary due to the increasing and diminishing current. 2d—Mutual induction between the primary and secondary. 3d—Self-induction in the secondary coil. The correct impression is best conveyed by the realization of the magnetic relationship between the coils when a core of iron of a continuous character permits the lines of force to freely operate upon both. The commercial value of the self-induction is found in its automatic regulation both of the energy entering the primary and the energy developing in the secondary. The mutual inductance between the primary and secondary is one henry, when the number of lines of force from the primary coil due to one ampere which interlinks the secondary coil, are equal to one hundred million. Or this may be stated by saying that "The mutual inductance of two coils is one henry when the passage of one ampere through one coil causes a total magnetic flux of 10^8 lines of force to be linked with the secondary coil."

The Transformer Iron.—Losses of power in the iron represent the exact amount of power wasted in eddy currents and hysteresis. Using a very high grade of soft iron of little coercive force will reduce the hysteresis, as this is entirely a molecular affair. But eddy currents are only reduced by laminating the iron; that is, using it in the form of thin sheets. The efficiency of a transformer is greatly dependent upon the character of its design in this respect. Such design is best obtained by the use of iron of the lowest coercive force and the highest permeability. For instance, if a transformer dissipates 500 watts out of 5,000, then the efficiency equals 4,500 ÷ 5,000 = 90 per cent. But the 500 watts wasted may be regarded as consisting of the following:

Loss of power in watts in the iron core due to eddy currents and hysteresis.................... = 150
Loss of power in watts in the primary coil due to the C^2R effect. = 150
Loss of power in watts in the secondary coil due to the C^2R effect. = 200
Total loss of power in the transformer due to all energy wasting causes........................ = 500



Efficiency curve of a transformer with various loads.

The Permeability of Iron.—The permeability of the iron employed is of such importance that an exact knowledge is required of the figures by which it is represented. In the following table the magnetizing force required and the permeability of sheet steel and annealed soft iron are given:

Magnetization Data of Mild Annealed Steel and Soft Swedish Iron at About 60 degs. Fahrenheit.

Lines of force per sq. centimeter.	Magnetizing force H required for		Permeability μ for	
	Annealed cast sheet steel....	Annealed soft iron.	Annealed cast sheet steel....	Annealed soft iron.
2,000	1.2	0.8	1,800	2,675
4,000	1.7	1.17	2,400	3,375
6,000	2.5	1.73	2,425	3,500
8,000	3.7	2.55	2,150	3,150
10,000	5·55	3.95	1,800	2,550
12,000	8.95	6.45	1,375	1,850
14,000	15.00	12.00	950	1,050
16,000	29.00	54.00	550	325
18,000	90,00	126.00	200	125
20,000	224.00	324.00	87	55

The act of magnetization is accompanied by certain phenomena as noted in the following synopsis: 1st—The fact that with a small magnetizing force, a comparatively large magnetic change takes place in the iron. This has been called by some authors the elastic stage. 2d—The fact that with a small additional force when a certain point in magnetization is reached, a comparatively complete magnetization takes place. This has been called by Fleming the catastrophic stage. 3d—The fact that with a great increase in the magnetizing force a very limited response occurs magnetically in the iron. To reverse this operation necessarily represents the absorption of power. This power, it seems, disappears in the effort to return the iron to its normal condition, and then reappears as heat. The iron will when heated, respond more readily to small magnetizing forces. Its permeability under this condition is increased. The entire action is that of the molecules of iron attracting each other so strongly that a certain amount of force is required not only to break this attraction as it normally occurs and rearrange them; but it is also required to bring them back to where they started from.

Calculation of Hysteresis in Iron.—It is best to realize that the quality of iron best suited to alternating current work, is iron of such a character that its coercive force is least. In magnetizing a piece of iron, the process may be considered in the following manner: First, the iron is magnetized by means of a coil of wire carrying a current. Its magnetization under such circumstances may be very high, in fact it may be saturated. The next step is to reduce and withdraw the current. When this is done, the iron if examined will be found to be still magnetized. In order to reduce this magnetization to zero, it will be necessary to use a certain amount of electrical energy in the reverse direction. It is quite evident that the greater the amount of energy required to accomplish this, the poorer the quality of iron is for transformer use. On the other hand, if the demagnetization of the iron is continued in the opposite direction until it reaches a point equally as high this way as the other, it is only to be expected that the same process must be followed out to bring it back to zero again. If, for instance, during the magnetization of the iron up to a certain point and its return to zero, five watts are consumed; then it would require five watts to reverse its magnetization up to the same point and back. The total during the entire operation would therefore be 5 + 5 = 10 watts loss. This complete operation is called a cycle of magnetization, and is due to the effect of a complete cycle of current in a coil upon a core of iron. If the cycles are 100 per second, the watts wasted in the iron would be 10 × 100 = 1,000 per second. It is readily seen that the further the magnetization is pushed the more difficult it is to reverse and complete the cycle without a comparatively great loss of power. But it is also evident that the quality of the iron, through which it absorbs energy, is the feature which regulates its value as to its use in transformer construction.

Permeability and Coercive Force.—The facts as thus presented, mark the difference between the permeability of the iron and the degree to which it absorbs energy during magnetization and demagnetization. Although iron may have a very high permeability, it does not necessarily follow that the coercive force required is therefore very low. This important point is represented by means of a diagrammatic sketch in which the magnetization of a piece of iron is represented with the return curve showing the extent to which the iron returns to its neutral condition. The greater the distance between the return curve and the zero point, the more the likelihood exists of the iron absorbing energy. These ideas are presented in the form of a series of sketches which show the retentiveness of the iron, the degree of coerciveness in the iron, and the processes involved in a complete cycle of magnetization.

Formula for Hysteresis.—Steinmetz investigated the relationship existing between a certain grade of iron and the amount of energy it absorbs. The examination of a variety of kinds of iron clearly indicated that the energy was absorbed in strict proportion to certain elements which were best considered in the shape of a formula as follows:

Hysteresis in ergs = a constant × (lines of force per square centimeter)$^{1 \cdot 6}$.

If the formula is represented symbolically the following values appear: H = ergs, B = lines of force per sq. cm., constant = .002, the formula then becomes: Hysteresis in ergs = .002 × $B^{1 \cdot 6}$. The reason why .002 is selected is because an examination of the various metals disclosed the following figures:

Hysteresis Constants for Various Grades of Iron.

Names of metal.	Constant.
Swedish wrought iron well annealed	.0010 to .0017
Annealed cast steel of good quality with little carbon	.0017 to .0029
Cast Siemens-Martin steel,	.0019 to .0028
Cast steel with plenty of carbon and wrought iron of poor grades	.0031 to .0054

The number of lines of force per square centimeter, raised to the 1.6 power, may try the ability and patience of readers, so Fleming's figures are given for iron magnetized from 1,000 to 10,000 lines of force per cubic centimeter. In addition the total value of the product of the constant and the lines per square centimeter given raised to the 1.6 power are presented. The results are given in ergs per cubic centimeter, but the ergs are easily transformed into foot pounds or watts if required. The last line of figures in the table, giving the ergs absorbed by a cubic centimeter of iron carrying 10,000 lines of force, according to the formula, would be equal to about 10 foot pounds per complete cycle of magnetization.

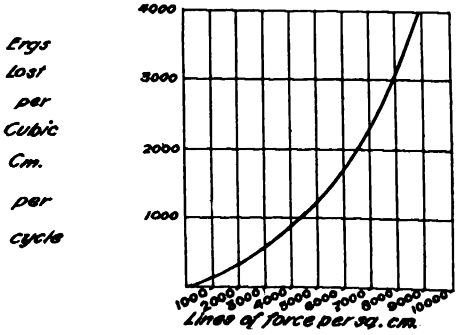
Table of Hysteresis Calculated by the Formula.

Lines of force per sq. cm.	Value of $B^{1 \cdot 6}$.	Value of .002 × $B^{1 \cdot 6}$.
1,000	63,100	126
2,000	191,300	383
3,000	365,900	732
4,000	580,000	1,160
5,000	828,800	1,658
6,000	1,111,000	2,222
7,000	1,420,000	2,840
8,000	1,758,000	3,516
9,000	2,122,000	4,244
10,000	2,511,000	5,022

As there are 10^7 ergs to a watt, it is evident the above table can be converted to English measure and watts if necessary. To illustrate the application of this table, consider the frequency of a commercial circuit carrying an alternating current as equal to 120 cycles per second. If the degree of magnetization is equal to 10,000 lines of force per square centimeter it will be equal to 6¼ × 10,000 or 62,500 lines of force per square inch. According to the table .002 × $10.000^{1 \cdot 6}$ = 5,022 ergs per cubic centimeter per cycle. This would mean 120 × 5,022 = 602,640 ergs; but as 10^7 ergs equal one watt, 602,640 ergs ÷ 10^7 or 10,000,000 will be equal to .06 of a watt per cubic centimeter. A cubic inch of iron is equal to 15.625 cubic centimeters, which would mean 15.625 × .06 watt per cubic inch, a value equal to .9375 watt. Averaging 1 watt per cubic inch would mean at this magnetization 1,728 watts per cubic foot of iron.

Choice of Iron.—The choice of iron for the various purposes to which it is best suited is found by an examination of the area of the hysteresis curve representing a complete magnetic cycle. As shown, the area must be large if a permanent magnet is to be constructed. On the other hand, the area is smaller where such iron is used for dynamo work. If transformer iron is to be selected the area is smaller still; in fact it must be small or the hystereis loss will be so great as to destroy the efficiency of operation of the transformer. The entire question of transformer design is related to the final question of lighting and power efficiency. To transmit electrical energy over a distance of many miles with economy it is necessary to limit the initial expense. This expense is divided up between the cost of the generating and receiving stations at each end and the investment required for the construction of the line. But the most important feature of this system is that of the transformation of the pressure up and down at each end of the power line.

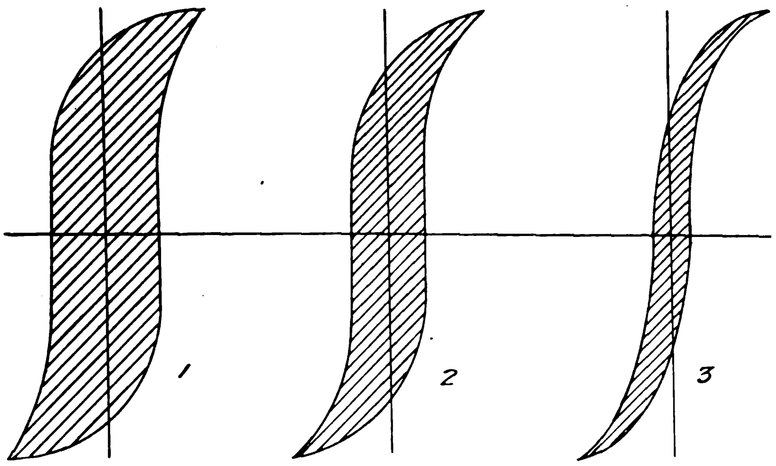
Curve of Hysteresis Loss.—Steinmetz constructed what is called the hysteresis curve in contradistinction to the hysteresis loops. The curve shows the relationship between the loss in ergs in the iron and the number of lines of force for a single cycle. The drift of the curve shows clearly the manner in which the losses in the iron grow with the increase in the magnetization. As long as the magnetization lies between zero and 5,000 lines of force the loss in ergs is slow in increasing. After passing this point, however, the rise is more rapid, and after the loss in ergs per cubic centimeter ex-



Steinmetz Curve of Hysteresis.

ceeds 2,000 the further loss increases rapidly. Dividing ergs by 10,000,000 or 10^7 will give watts; it is therfore a simple process in the calculation of hysteresis to judge of the relative value of different grades of iron by this means of comparison.

Principles of Design.—Not only in transformers, but in the armatures of direct current dynamos and in the moving iron parts of many alternators hysteresis occurs. The checking of it is one of the purposes of scientific investigation as well as the limitation of other sources of loss. With regard to transformers, the following conditions must be observed:



1—Area of curve large; metal suited to make permanent magnets. 2—Area of curve smaller; metal suited for dynamo magnets. 3—Area of curve very small; iron good for transformer construction.

First—The iron core loss must not represent more than 3 to 4 or if possible 1 to 2 per cent. of the total load in watts. One per cent. is not too high for large transformers of many kilowatts.

Second—The drop in volts in the secondary must not be more than 1 or 2 per cent. of the total secondary pressure.

Third—The core must be kept cool by allowing at least 3 to 4 square inches of radiating surface per watt wasted in the iron.

Fourth—The winding of both primary and secondary coils must be large enough to radiate the heat they generate through C^2R loss. An allowance of from 2 to 3 square inches per watt wasted must be provided in the coil surface.

Fifth—Insulation of the best quality is necessary to withstand high pressures.

Sixth—Additional ventilation and cooling must be supplied to keep down the temperature of large transformers. Air blasts and oil are the favorite methods in vogue at present.

The recent electrical exhibition in London was such a financial success that the executive committee has been able to refund to the exhibitors much of the money they paid for space.

ELECTRIC FURNACES.[*]

BY J. H. STANSBIE, B.SC., F.I.C.

The main object of this paper is to introduce to you simple forms of electric furnaces which can be readily fitted up for experimental purposes. The literature of the subject is rapidly becoming voluminous, especially that which refers to the specifications of patents. Every known principle seems to have been appropriated in the hope that something useful may be covered, but in spite of its many successes the application of the electric furnace for industrial purposes is still in its infancy, and there is much hope for its future.

Electric energy may be converted into heat in a variety of ways, and the chief of these have been utilized for electric furnace work. Electric furnaces may be divided into two main classes: First, electro-thermic, in which the heat equivalent only of the electric energy passing into the furnace is utilized for producing physical, chemical and metallurgical changes; second, electrolytic, in which part of the energy of the current is used up directly in effecting chemical changes, and the remainder for heating effects. The first class only will be dealt with in this paper.

There is only one direct way of converting electrical energy into heat, and that is by putting material resistance into the path of the current which is carrying it. This resistance may be furnished by either a solid, a liquid or a gas. If the resistance is offered by solid or liquid matter the apparatus is known as a resistance furnace, but if by gaseous matter it is an arc furnace. A large number of furnaces, both experimental and industrial, arrange themselves under these heads, and there are several sub-divisions according to the particular way in which the principles are applied. In the majority of these furnaces the resistance is in the path of the primary current. There is, however, a resistance furnace in use which does not appear to have passed through the laboratory stage, but to have been developed at once for industrial purposes. It is based upon the transformer principle, and consists of a cored coil for carrying light alternating currents of high potential surrounded by an annular space or hearth lined with refractory material in which a continuous circuit of the metal under treatment carries the heavy induced currents of low potential, and offers the resistance necessary to develop sufficient heat for its fusion. Its best known form is the Kjellin furnace, although others claim to have introduced important modifications. Kjellin uses currents of 80 to 90 amperes at a pressure of 3,000 volts in the primary, and 30,000 amperes at seven volts in the ring of metal in the hearth, which has a capacity of 35 cwt. of steel. Furnaces of this type having a capacity of a few pounds should prove very valuable for the preparation of pure metals.

In resistance furnaces generally the resistance is either in or out of contact with the material to be heated, or the material itself offers the resistance. Also, either direct or alternating currents may be used, the most economical being heavy currents of low pressure. Hence it is necessary to use transformers with alternating currents brought from a distant power station. The terminals by which the current is led into and out of the furnace are almost invariably carbon rods or blocks, although water-cooled metal electrodes have been used. In some furnaces a combination of arc and liquid or solid resistance is found most useful, and in this case the pressure must not be too low.

At present the ideal source of the mechanical energy for dynamos and alternators is water power, and where this can be obtained the electric furnace flourishes. The enormous loss of energy taking place between the stoker's shovel and the fly-wheel of an engine puts the direct combustion of solid fuel out of court, but the use of gaseous fuel direct, especially of the waste gas from blast furnaces, will much improve the chances of electro-thermic processes being made successful generally. It is estimated that about 500,000 hp. developed from falling water is being used in electric furnaces for the production of aluminum, carborundum, calcium carbide, graphite, iron, steel, ferro-alloys, etc. The Acheson furnace for carborundum, the Heroult furnace for steel-making, the Stassan furnace for ore reduction, and the Keller furnaces may be mentioned as being in use in successful industrial processes, while the number of furnaces being used for the manufacture of calcium carbide is very large.

---

[*] Abstract of paper read before the Birmingham (Eng.) Electric Club, November 4, 1905.

Experimental Furnaces.—A small resistance furnace for demonstrating the melting of metals is readily made by chipping the large face of a firebrick so as to form the cavity and two semi-circular channels running from it to the ends of the brick. A second brick with a shallower cavity and similar channels serves for the top. The cavity forms the hearth of the furnace, and the channels allow of the introduction of two carbon rods which are fixed with their ends just projecting into the cavity. The metal is placed in the cavity, and covered with a layer of small pieces of carbon so arranged as to fill up the space between the carbon rods. (Arc carbons broken up serve the purpose very well.) The top is placed in position and the current switched on. The temperature rises rapidly and a charge of cast-iron is soon melted. This can be run from an inclined tap hole passing through the bottom of the cavity by plugging the upper end with a piece of the metal before charging. The metal plug melts last, and the whole charge runs from the furnace in a continuous stream. A vertical section of the furnace is shown in Fig. 1. A slight modification of this furnace enables it to be used with a carbon tube. For this purpose an inclined channel is made in the walls of the hearth at right angles to the length of the bricks to hold the tube, the ends of which project from the sides of the furnace. The cavity is filled with carbon fragments to surround the tube and connect the rods. On passing the current into the furnace a rapid increase in temperature takes place, and substances to be experimented with can be readily introduced into the tube. Reductions and fusions are rapidly effected. The tubes are easily made by drilling pieces of arc carbon of requisite length. See Fig. 2, which shows the furnace in vertical transverse section.

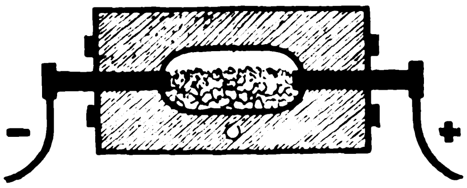


FIG. 1.

A small arc furnace of the Siemens type is easily fitted up. A hole is drilled in the side of a carbon crucible, and a carbon rod fitted tightly into it. The crucible is placed in a cavity in a fireclay block, which also supports the carbon rod along part of its length. The block is placed on a small iron table having a vertical rack motion, and a carbon rod to act as the positive electrode is fixed vertically over the crucible. When the charge has been introduced and the current switched on, the arc is readily struck by raising and lowering the table. The operation can be regulated by the same means. Fig. 3 shows the furnace in vertical section.

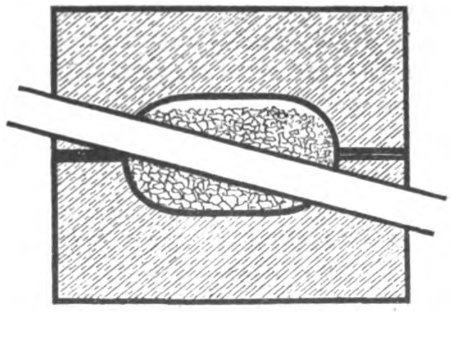

FIG. 2.

A more durable form of the Moissan lime furnace can be made with strongly compressed magnesite bricks. Two of the bricks are chipped out on corresponding faces, so as to form the crucible cavity and the channels for the carbon rods. They are then braced firmly together, and the top formed by a third brick, hollowed out a little to correspond to the cavity below. The electrodes are carbon rods, 1 inch diameter and 15 inches long, having a copper electro deposited on part of their length to insure good contact. The reactions are carried out in a shallow carbon crucible, and the majority of the fusion and reduction experiments requiring very high temperatures can be made in it. Chromium and molybdenum are readily reduced from their oxides. The current used in these furnaces varies from 100 to 200 amperes at a pressure of 110 volts in the mains.

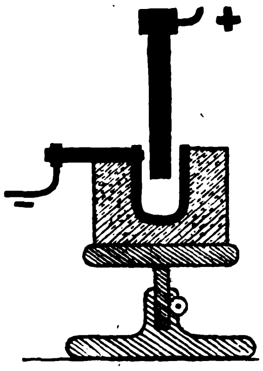

FIG. 3.

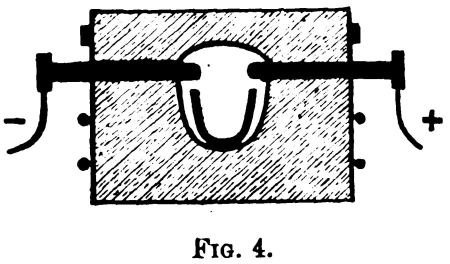

FIG. 4.

A good idea of the interest taken in electric smelting by those who are in position to deal with the subject practically, can be obtained from a review by M. Minet in the "Electro-Chemist and Metallurgist" for December, 1904. No less than 260 references, exending from Davy's work with the alkalies in 1808 to the present day, are given, and some 40 of these refer to calcium carbide alone. This shows that much attention is being given to reactions which take place at exceptionally high temperatures, and for the elucidation of which M. Moissan has done so much. One of the latest developments is that dealing with tantalum, the cheap production of which bids fair to mark an epoch in the history of incandescent lighting.

LEAD-COVERED WIRING.*

BY JOHN D. MACKENZIE.

The wiring problem—like the poor—we have always with us—either in the description of a new system or the acclaiming or declaiming of an old one. But of all the various systems—and they are legion—lead-covered wiring is, perhaps, the one on which we have the greatest diversity of opinion, the advocates of the system being quite as dogmatic in their support of it as its opponents are in denouncing it. Yet really, when all is said and done, there is no system of electric wiring which can be regarded as a universal panacea for the ills that electric wiring is heir to, and so finally, it comes to be a case of adjustment of pros and cons in order to decide which system is the best for each particular instance. If wiring contractors and consulting and municipal engineers could study each case absolutely on its merits, without any predisposition or bias, and recommend the system best suited to meet all the circumstances, the quality and durability of electrical installations, as a whole, would be instantly put on a higher level than it is at present.

In the following remarks I shall endeavor to place the advantages and disadvantages of lead-covered wiring side by side, and show how some of the disadvantages may be minimized.

Advantages.—1. The wire comes to the contractor, already provided with its own continuous metallic sheathing, and generally requires no further protection.

---

*From the "Electrical Review," London.

2. The sheathing is water-tight, and the whole installation can quite readily be made so too.

3. The great flexibility of the wire enables it to be installed with much less damage to buildings.

4. The small diameter of the wire enables it to be used in surface work, where any other system would be an eyesore.

5. The difficulty of making joints practically compels the adoption of a loop-in system.

The disadvantages urged against the system are many and various, but fall under two general heads, viz.:

1. Risk of injury during erection.
2. Risk of injury after erection.

To that, some add the risk of injury during manufacture. This, however, with the exception of one point, is no greater in lead-covered than in the ordinary taped and braided wiring. The one point of difference is in the heating to which the wires are subjected during the process of sheathing. Considering, however, the rapidity with which the wires are run through the lead press, and the tests which are afterward applied to these cables, and which they successfully stand the risk of damage seems very slight.

Before dealing more fully with the disadvantages attendant on the use of lead-covered wires, it may be as well to point out that, personally, I have no love for twin wires, either round or flat, considering it inadvisable, to say the least, to run the chance of an internal short-circuit inside a soft metal sheathing. It is far preferable to use single lead-covered wires, with the lead sheathing properly bonded and earthed, because it then requires two "earths" one on each wire before one obtains a short-circuit, and on public supply systems an "earth" on the live wire means the blowing of a fuse. For these reasons, I do not intend to deal here with twin wires.

The risks of injury during erection, arise from the carelessness of the wireman, and from the carelesness of other workmen.

The careless wireman cuts into the insulation when stripping off the lead sheathing; overheats and softens the insulation when sweating the sheathing into boxes for a water-tight system; overlooks the pin-holes caused by heated air bursting through the melted solder at such boxes; pulls the lead sheathing too hard, so making it brittle, and then it cracks when bent: hammers on his saddles too tight, and perhaps puts them on twisted, so cutting the lead by the edge of the saddle.

The carelessness of other workmen is shown—by the the plasterer who cuts the lead with his trowel; the laborer who drops a shovel on it; the joiner who nails the flooring board to it; and by any man who walks with hobnailed boots over the top of it.

The risks after erection are:

(a) The lead gives very little mechanical protection, from nails, for example.

(b) It may be successfully attacked by rats and mice.

(c) If a failure of insulation takes place, a wire cannot readily be withdrawn and replaced.

(d) Lead expands with increase of temperature, and may not go back to its original length when cold, and hence it may come in contact with other metals, or may even get cracked and broken.

(e) The electrical resistance of lead being high, contact with other metals may form a better "earth" than the proper earth connection.

(f) When an "earth" comes on, the lead may fuse at the point of contact as quickly as the fuse wire does.

(g) Pure water in the presence of air, and water containing salts in solution, such as ammonia, have a solvent action on lead.

(h) Decaying animal or vegetable matter under floors, etc., produce acetic acid, which, acting on the lead sheathing, has also a deleterious effect by forming "white lead."

(i) The presence of other metals, such as brass saddles in damp situations, causes electrolytic action.

(j) Where the lead sheathing is bared back to allow the wire to enter a switch or other fixture, there is a tendency for the current to creep on to the lead and escape at some other point, causing electrolytic corrosion.

The above list of defects, disadvantages, and possible risks of injury follows, with some variations, a very full arraignment of lead-covered wires, and I take it to represent all, or nearly all, that can be said against the system.

The next point which arises is the question, "Is it possible to overcome or minimize the risks?"

Taking the careless wireman, it is quite possible to get careful workmen who will do none of these things; and, in any case, will a careless workman not cut into the insulation when removing braiding from ordinary wire—will he not twist and kink the wire when drawing it into conduit, will he not leave ragged edges on his conduit so as to tear the insulation, will he not attempt to draw too many wires into a conduit, so straining the insulation and breaking the strands of wires; in short, what will the careless wireman not do? Ergo, get rid of him as quickly as you can.

The risk of injury from other tradesmen is always present, and where lead-covered wiring has to be carried out while a building is in course of erection, special precautions must be taken to avoid injury—e.g., laying temporary boarding over the runs of wire on the floors, lapping up with tape where coming out through plaster work, etc.

The faults after erection make the most formidable list, but it is quite possible to minimize these considerably.

(a) This point is made a good deal of by the opponents of lead-covered wiring, but seems to me to be grossly exaggerated. During the last seven years I have only had three instances in which lead wiring was damaged through nails or similar articles having been driven through the plaster work.

(b) This again is much exaggerated. Rats and mice have teeth which can easily work havoc on lead wire, but they seldom do so, and my own personal experience supplies no instance. These rodents will only attack lead wiring or lead water-pipes when in the direst straits for food or drink.

(c) This is the only point where conduit systems can show any real superiority over the lead-covered. The usual method of lead-covered wiring is to plaster it right in, and consequently it is impossible to withdraw it without damage to the plaster work. Several years ago the writer adopted the system of putting thin close-joint tubing in such walls as would be plastered up solid, dropping the lead-covered wires down this tube and drawing them taut, then placing an insulating bush top and bottom of tube, thus giving the advantage of a conduit system and also some more protection against an exploring nail.

(d) Here we have a fault not so much due to the lead-covered wire as to its indiscriminate use. Where wiring is to be subjected to very great variations in temperature, lead should not be be used, but the writer has never found the ordinary temperature changes in house or shop to have any appreciable effect on the lead sheathing.

(e) In order to overcome this all that is necessary is to bond all the lead wires together at frequent intervals, and so get the advantage of all the sheathing. For this purpose the writer uses a solder containing a large proportion of lead, and has found no trace of electrolytic action even in damp situations after years of use.

(f) The foregoing method of bonding the wires together tends to prevent the lead sheathing melting before the fuse does.

(g and h) The solvent effects of water with either air or salts in solution are certainly a possible disadvantage, but no more so than with thin enameled conduits, which rust through in a very short time. Except under very exceptional circumstances, the amount of acetic acid which can be formed by decaying matter will not seriously harm the average lead-covered wire,

(i) Electrolytic action between brass saddles and the lead sheathing may quite easily be overcome by the use of lead saddles, which are quite as efficient.

(j) The current creeping along the insulation and on to the sheathing and causing electrolytic corrosion, is also easily overcome by dipping the ends of the wires up to the sheathing in melted joint-box compound. This also helps to increase the insulation resistance of the whole job.

The faults which so often occur on lead-covered wiring are all due to carelessness in the workmen, or because the conditions under which the wire is to work have not been properly appreciated. And the advantages to be obtained by the use of lead-covered wire makes it easily worth the time spent in considering all the necessary circumstances. An example of what not to do was given a good many months ago in a letter published in these columns, where lead-coverd wire has been drawn into the iron gas pipes laid in the ground, with the inevitable result, viz., breakdown.

Here the lead covering was no doubt scratched, and perhaps cut while being drawn in, by the roughnesses inside the tube and then it lay touching the iron and perhaps surrounded by moisture, either leaking in through the pipe joints or due to condensation inside the tube, thus giving the very best chance for electrolytic action.

No one knowing the limitations of lead-covered wire would suggest or carry out such an arrangement, instead of which the wire ought to have been laid either in wood troughing and pitched in solid, or drawn into smooth earthenware or concrete conduits. It is the adoption of such obviously foolish arrangements, as indicated, which has given lead-covered wiring a name for want of reliability, and I trust the foregoing remarks may indicate, in some small measure, how to overcome some of the difficulties.

General Electric's New Stock.

The directors of the General Electric Company decided to recommend the issue of a little more than half of the $11,674,500 increased capital stock authorized at a meeting of the stockholders on November 1 last. The amount to be issued is $6,033,000, and the stock will be offered to stockholders for subscription at par to the extent of 12½ per cent. of their present holdings. This would amount to about one share of new stock for every eight shares of existing capital.

The special meeting of the stockholders to ratify the issue of $6,033,000 new stock, well be held at Schenectady, December 5. Further details as to the date of the new issue, and the time and manner in which payment will be required to be made will be announced shortly after that meeting.

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until December 12 for furnishing Eastern Navy Yards with the following electrical material: Schedule 246, electrical wire and supplies; schedule 247, generating sets; schedule 249, zinc anodes. Blank proposals can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington.

On December 26 the Bureau will open bids for furnishing Western Navy Yards with the following: Schedule 254, searchlight; schedule 255, motors, zinc plates, etc. Blank proposals can be obtained upon application to the Bureau.

Sealed proposals are being invited until January 5, 1906, for the installation of the electric wiring and conduit systems of two laboratory buildings for the Department of Agriculture. Specifications and detailed information can be obtained upon application to the building committee, Department of Agriculture, Washington, D. C.

ELECTRICAL PATENT RECORD

LETTERS PATENT ISSUED NOV. 21, 1905.

Electric Railways and Appliances.

804,914. Car-Fender. George Allen, Franklin, Pa. Filed July 8, 1905.

805,062. Guard for Third Rails. Augustus A. Hickerson, Reynoldsburg, and William H. Phalor, Sheppard, O. Filed Feb. 6, 1905.

805,096. Trolley-Wheel and Mounting Therefor. Frank N. Russell, Elmira, N. Y., assignor of one-half to Albert D. Lane, Shoshone Agency, Wyo. Filed April 15. 1905.

805,166. Electric Rail. Louis Steinberger, New York City. Filed Jan 3, 1905.

805,225. Electric Trolley-Switch. George H. Negley and Isaac L. Brown, Indianapolis, Ind. Filed Sept. 11, 1903.

805,311. Fender. John L. Matthews, Hydepark, Mass, Filed Aug. 1, 1905.

805,338. Cable-Trolley. John E. Boyle, Scranton, Pa. Filed Nov. 12, 1904.

805,408. Trolley-Wheel. Thomas Broadbent and Israel Hey, Wollaston, Mass. Filed June 17, 1904.

Electric Lights and Appliances.

805,131. Incandescent Electric Lamp. Royal Gerow and George A. Gerow, Northport, Canada. Filed Dec. 31, 1904.

805,248. Electric Lamp. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed May 8, 1899.

805,282. Incandescent Lamp. Gustavo Germani, Pittsburg, Pa. Filed Oct. 13, 1904.

805,287. Incandescent-Lamp Socket. James J. Hartley, Syracuse, N.Y., assignor to the General Electric Company. Filed May 1, 1903.

805,292. Method of Starting Electric Gas or Vapor Devices. Peter C. Hewitt, New York City, assignor to the Cooper Hewitt Electric Company. Filed Nov. 24, 1903.

805,322. Electric-Arc Lamp. William R. Ridings, Stretford, Eng., assignor to the Westinghouse Electric & Manufacturing Company. Filed March 1, 1904.

805,370. Electric-Light Shade or Hood. Albert S. Marten, East Orange, N. J. Filed March 23, 1904.

Electrical Machinery and Apparatus.

804,849. Electric Switch. Frederick Huffer, New York City. Filed April 9, 1904.

805,092. Electric Transmitter. Jerome Prince, Milford, Mass., assignor of parts to Charles E. Aldrich and John H. Macdonald, Beverly, Mass. Filed Feb. 2, 1905.

805,188. Apparatus for Controlling Electric Motors. Harry E. Day, Brooklyn, N. Y., assignor to Ernest R. Esmond, New York City. Filed May 5, 1899.

805,249. Electric Conductor. Louis E. Underwood, Lynn, Mass., assignor to the General Electric Company. Filed April 1, 1905.

805,263. Time-Limit Device for Controllers. Alexander Churchward, New York City, assignor to the General Electric Company. Filed Oct. 10, 1903.

805,289. Magnetic Separator. Harry E. Heath, Windsor, Conn., assignor to the General Electric Company. Filed Sept. 17, 1903.

805,291. Semaphore-Signal. Reinhold Herman, Crafton, Pa., assignor to the General Electric Company. Filed April 26, 1905.

805,346-415. Alternating-Current Motor System. Albert G. Davis, Schenectady, N. Y., assignor to the General Electric Company. Original application filed April 4, 1898. Divided and last application filed April 9, 1902.

805,416. Electric Motor. Ernest R. Esmond, New York City. Filed Aug. 23, 1901.

Telephones and Telephone Apparatus.

804,848. Telephone Signal System. Amiel R. Hoover, Pleasanthill, Ill., assignor of one-half to C. J. Craigmiles, same place. Filed April 20, 1905.

804,861-862. Multiple Switchboard for Telephone-Exchanges and Telephone Exchange System. Milo G. Kellogg, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Feb. 13, 1893, and Dec. 20, 1894.

804,946. Electric Switch or Disconnecting Device for Telephones. Leonard J. Fletchall, Hatfield, Mo., assignor of one-half to Mark L. Belden, same place. Filed Aug. 11, 1904.

805,126. Multiple-Station Telephone System. Arthur J. Farmer, Detroit, Mich. Filed Dec. 26, 1903.

Miscellaneous.

804,819-820. Signaling System. James E. Allison, St. Louis, Mo., assignor to George M. Seeley, New York City. Filed Aug. 14, 1902, and May 4, 1904.

804,843. Leading-in Conductor for Electric Vapor Apparatus. Peter C. Hewitt, New York City, assignor to the Cooper Hewitt Electric Company, same peace. Filed March 26, 1904.

804,931. Apparatus for Electrolytical Decomposition. Gunnar E. Cassel, Stockholm, Sweden. Filed May 4, 1905.

805,057. Ringing Key. Edward B. Craft, Chicago, Ill., assignor to the Western Electric Company. Filed April 8, 1905.

805,108. Signalling System. Paul Winsor, Weston, Mass. Filed Aug. 11, 1905.

805,167. Insulator-Pin. Louis Steinberger, New York City. Filed Jan. 3, 1905.

805,169. Insulator and Wire-Clamp. John F. Taubold, Scranton, Pa. Filed Feb. 26, 1904.

805,260. Insulating-Bushing. John G. Callan, Lynn, Mass., assignor to the General Electric Company. Filed Aug. 28, 1902.

805,327. Electric Self-Winding Clock. Charles F. A. Sturts, San Francisco, Cal. Filed June 13, 1904.

805,412. System for Wireless Telegraphy. Thomas E. Clark, Detroit, Mich., assignor to the Thomas E. Clark Wireless Telegraph-Telephone Company. Filed Feb. 17, 1902.

THE TELEPHONE WORLD.

Expansion for United States Company.

The directors of the United States Telephone Company held a lengthy meeting in Rochester, N. Y., last Thursday evening. Two points settled at the meeting were expansion of the Stromberg-Carlson plant in Rochester, and the installation of a new plant in St. Louis. President Thomas W. Finucane practically admits that the capacity of the Stromberg-Carlson plant will be doubled, and that the St. Louis plant will be capitalized at $6,000,000.

"The matter of the New York franchise did not come formally before the meeting," said Mr. Finucane, "but was, of course, discussed by the directors. You can say that we have the same kind of a franchise in New York City that the Bell Company has. The Bell has invested $50,000,000 on the strength of its franchise, and if that franchise is no good, then ours is not. Both franchises are similar, and our franchise is just as good as theirs. That's all there is to say on the subject at present. We will wait until the corporation counsel of New York renders his decision before we do anything further."

The stockholders of the Frazeysburg, O., Independent Telephone Company, which was recently incorporated with a capital stock of $10,000, has the following officers: President, Max Frazier; vice-president, Dr. W. S. Drake; secretary and treasurer, S. H. Frazier; general manager, J. B. Rhodes; assistant general manager, Emmett McCann; counsel, Sherman M. Granger. The company has purchased all the property of the Farmers & Merchants' Telephone Company in Muskingum County, including the Frazeysburg exchange and 28 miles of farm lines. A toll line will be built connecting with the lines of the Zanesville Telephone & Telegraph Company and the United States Telephone Company. The system will be improved and an extensive farm line development made.

Application has been made for a charter for the Citizens' Telephone Company of Hartford, Conn. This is an Independent company and will have a capitalization of $1,000,000, with the privilege of increasing this to $10,000,000 as necessary. Mr. D. A. Reynolds, of the State Line Telephone Company of New York City, is one of the leading promoters in the enterprise.

The Wexford County, Mich., Independent Telephone Company has been organized. The company is capitalized at $1,000, and expects to increase the capitalization to $5,000. The officers are: President, G. A. Lake; vice-president, A. B. Southick; secretary, D. L. Rose; treasurer, R. D. Frederick.

Franchises were lately granted by the Doylestown, Pa., town council to the Bell and Keystone State Telephone Companies, who are required to construct an underground system. The companies are enjoined to pay $100 each into the borough treasury for the franchises, the first time any such action has been taken.

The Drain, Ore., Water, Light & Telephone Company has been organized by Ira Wimberry, Benton Mires, W. W. Kent and others.

To Rebuild Four Exchanges.

The Wisconsin Telephone Company has completed plans for the rebuilding of the exchanges at Kaukauna, Appleton, Neenah and Menasha. A new office building will also be erected at Appleton. Two additional copper circuits will be be built from Kaukauna to Appleton, Manitowoc and Green Bay, making six circuits to Appleton and four each to Manitowoc and Green Bay.

Daniel P. Powers, who has been manager in Kaukauna for the company for the past four years, has been promoted to the position of general traffic manager of Wisconsin, with headquarters at Milwaukee. He will be succeeded by F. T. Fallowens, of Winona, Minn.

Telephone Socials in Kansas.

A new social function has been invented by the farmers of Dickinson County, a telephone social. When the telephone owners south of the river wished to build a line to connect with the line north of the river they gave a box social instead of making an assessment. They cleared $40 and built the line. The farmers have more than 1,000 telephones in operation in that county.

The Indian Creek Telephone Company has been organized at Cortland, Neb., by the election of the following officers: H. M. Huestis, president; B. E. Ridgley, secretary; B. B. Jackson, treasurer. The officers also comprise the executive committee, and were authorized to purchase supplies, etc., as soon as possible with a view to putting this line in operation before cold weather sets in.

The Diamond State Telephone Company of Dover, Del., is anticipating a great increase in its business during 1906, and has placed with manufacturers large orders for instruments and material in order to meet the requirements of the development of the telephone service of the Peninsula.

New Milford, Ill., will have a telephone system, a meeting having been held recently at which the officers and directors of the New Milford Telephone Company were chosen and plans made for the construction work. T. W. Evans was elected president.

Recent news from Missouri states that the Spring River Mutual Telephone Company has been granted a franchise to erect a telephone line on the public highway from Carl Junction through Waco to Asbury, and the Lafayette Telephone Company has been granted a 20-year franchise.

The Morris Telephone Company, with its principal office in Roxboro, N. C., was lately formed with $100,000 capital. The incorporators are T. H. Street, R. J. Teague, A. C. Boyles and G. D. Morris.

The exchange building for the Meridian, Miss., Home Telephone Company, is rapidly nearing completion, and will when finished, be one of the finest buildings in that city, as well as the best equipped in the State for telephone service.

Bigelow, Minn., boasts of having a telephone company with four stockholders.

Wisconsin Independents to Hold Convention.

The Independent Telephone Association of Wisconsin will hold its annual convention in Milwaukee, December 20 and 21. The headquarters will be at the Pfister Hotel. The Wisconsin conventions have always been held in February, but the date has been changed to December, as it is considered a more favorable time. An interesting programme has been prepared, and the usual large attendance is expected. Mr. H. C. Winter, Madison, Wis., is the secretary and treasurer.

Telephone Deal Closed.

The Indianapolis telephone deal, by which Toledo, O., and St. Louis, Mo., syndicates have secured a majority of the stock in the new Independent Telephone Company for $70,000, has been closed. C. E. Stinson, formerly manager of the Home plant in Toledo, has taken charge of the Indianapolis property, together with its long distance lines, and he has already reduced the running expenses $20,000 a year.

Temporary certificates have been issued of the underwriting and a voting trust has been established. The trust now controls more than 90 per cent of the stock. New certificates, which will be more negotiable than those now held by the purchasers will be issued in less than a month.

The Fairbury, Neb., Telephone Company is rebuilding its lines. A short time ago the capital stock of the company was increased to provide $15,000, the approximate cost of the projected improvements. The Fairbury company has practically won its fight against the Bell corporation in the town, and will be able with a rebuilt system to make good its pledges to the people and give good service at low rates and keep all the money in its locality.

The Star Independent Telephone Company of Star, Idaho, capitalized at $10,000, has been formed to establish a telephone system in that place, and will also establish long distance connections with Boise, Meridian, Nampa, Caldwell, Pearl, Emmet and Fayette. The incorporators are: H. D. Andrews, J. S. Clark, L. B. Wehr, A. S. Bixby, S. S. Foote and A. W. Hall.

The Independent Telephone Company of Yankton, S. D., has commenced construction work on its extension of the long distance telephone line from Gayville to Sioux City, connecting with the toll lines of the New State Telephone Company, and the Sioux City Telephone Companies.

The Riverton & Delmar Telephone Company has filed articles of incorporation to construct and operate telephone and telegraph lines in Delaware. The capital is $50,000, and the incorporators are mostly of Delmar. Riverton is in Maryland and Delmar is on the Delaware-Maryland State line.

Work is well under way on the new telephone exchange which is being installed in Ensley, Ala.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Abbeville, La.—The town council and water works committee of this city at a recent meeting informally discussed the water plans submitted and the advisability of acquiring an electric lighting plant in connection with the system.

Aberdeen, Miss.—This city is arranging to enlarge the electric light plant. J. M. Acker, mayor.

Bickleton, Wash.—H. T. Latham, of this place, is figuring on the installation of an electric lighting plant here.

Carleton, N. B.—A new electric light station is being talked of for this city, and from it light not only the city streets, but also the west side public buildings, warehouses, etc. The committee, under the chairmanship of Alderman Frink, is securing information as to the cost of a plant, etc., and one also considering an addition to the North End plant.

Castledale, Utah.—J. W. Seeley and C. L. Allen have been granted a franchise to construct and operate an electric light plant here.

Cleveland, O.—Mayor-elect Bernard Miller, of Lakewood, is getting proposed legislation into shape for the city council. A number of improvements are projected for the next year. The first matter to receive the attention of the new administration will be increased electric lighting facilities. An additional 500 hp. dynamo with a new boiler will be installed.

Coalville, Utah.—The city council has approved the plans and specifications for the power house for the electric light plant.

Escondido, Cal.—The city council has received an application from Hugh F. Duff for a franchise to establish an electric light plant and system here. Favorable action was taken and the franchise was ordered drawn and advertised for four consecutive weeks.

Eugene, Ore.—The city council has passed a resolution providing for the issuing of bonds to the amount of $100,000, the proceeds to be used in the construction of an electric municipal lighting plant.

Ft. Worth, Tex.—There is talk of outlining a plan for the betterment of the electric wiring conditions of this city.

Junction City, Ore.—J. N. Fellmer is preparing to erect an electric light plant here.

Lombard, Ill.—The Lombard Utility Company, capitalized at $2,500, will operate an electric light plant. The incorporators are S. J. Lombard, J. W. Burdette and S. W. Norton.

New Orleans, La.—The city council is negotiating for the purchase of the electric lighting plant now owned by a private company.

Potsdam, N. Y.—Justice Henry T. Kellogg, of the Supreme Court, lately rendered a decision restraining this village from building a municipal electric lighting plant, permission not having been obtained from the State Gas Commission, although the resolution to build the plant was adopted by voters nearly three months before the law creating the State Gas Commission went into effect.

Richfield, Utah.—A. J. Poulsen is promoting the organization of a company to install an electric power plant for the purpose of developing electricity for use in the Gold Mountain and Silver Valley districts. Mr. Poulsen plans to erect a plant at a cost of $60,000.

Roseburg, Ore.—The electors of this place have voted in favor of issuing bonds to the amount of $200,000 for the purpose of constructing a municipal electric light and water plant.

Santa Ana, Cal.—The trustees have instructed the city attorney to formulate a resolution calling for an election to vote on the question of issuing bonds for the purpose of constructing a municipal gas and electric lighting plant.

Sioux Falls, S. D.—The proposition to bond this city in the sum of $35,000, to build a municipal electric lighting plant was lately carried.

Steelton, Pa.—The Electric Light Company's plant was lately destroyed by fire. The loss is $60,000 and no insurance.

Tecumseh, Neb.—H. H. Herndon, a promoter from Adams, has been here endeavoring to interest the city council in giving up the electric lighting plant for a company he proposes to organize. For some time the plant has been inadequate, and Mr. Herndon proposes to install a modern plant and run all night.

Williamston, S. C.—The Williamston Cotton Mill of this city will install an electric light plant.

Woodward, Okla.—W. K. Palmer, 718 Dwight Building, Kansas City, Mo., has received the plans and specifications for the new electric lighting plant at this place.

STREET RAILWAYS.

Denver, Col.—A million dollars will be expended by the Denver & Rio Grande Railway Company in installing an electric lighting system for the road.

Duluth, Minn.—A movement is said to be on foot to organize a stock company to build an electric line from West Duluth through New Duluth and Fond du Lac to Carlton and Cloquet.

Freeport, Ill.—There is a strong likelihood that the Freeport & Dixon interurban electric line will be built next season.

Greenville, Pa.—The Shenango Traction Company, which proposes to build a line from New Castle to Meadville via Sharon, Sharpsville and this place, will on December 4 make application for charters for several lines.

Kalamazoo, Mich.—Engineers have completed a survey of a proposed electric line between Elkhart, Ind., and Pavilion, Mich., which if completed, as they say it will be, will make another interurban for this city.

Knoxville, Tenn.—The Knoxville & Maryville Electric Railway Company is the name of a new organization capitalized at $100,000, the purpose of which is to build 16 miles of railway from here to Maryville.

Milwaukee, Wis.—The Milwaukee Electric Railway Company will extend its interurban line from Waterford to Rochester, Burlington and Lake Geneva.

Mobile, Ala.—The Birmingham Railway, Light & Power Company contemplates, it is said, the construction of a trolley line over the proposed Red Mountain Road in the event of its being built by the city and the county.

Ossining, N. Y.—A trolley line is to be built in Westchester County, to extend from here to the new Croton Dam, thence to Croton-on-Hudson, Oscawana Crugers, Montrose and Verplanck's Point.

Rutland, Vt.—The Vermont Internal Improvement Company has been organized here with a paid-up capital of $100,000. Its business will be the buying, selling and leasing of electric railways in Vermont, with a charter granted in 1902, which is practically unlimited as to scope, and permits the increase of capital into the millions if necessary. The officers are: President, G. Tracy Rogers; vice-president, Leo H. Wise, of New York City; secretary and treasurer, Charles H. West, of this city.

Selinsgrove, Pa.—The borough council at a special meeting granted a right-of-way for an electric trolley line through the main streets of this place.

Skowhegan, Me.—There is talk of a third rail electric line from this town to Farmington, to run through the villages of Norridgewock, Mercer and others.

Springfield, Ill.—The Secretary of State has incorporated the Joliet & Southern Traction Company, which intends to build a road from Joliet through the counties of Will, Grundy and Livingston to Dwight.

Sturgeon Bay, Wis.—An electric line from this city to many of the towns of the North is likely to become a reality.

Union City, Mich.—It is reported that another electric line is to go through this city.

Waynetown, Ind.—The right-of-way is being secured near this town for the new traction line. Eli Baker and Ed. Reynolds are interviewing the farmers in regard to the matter.

POWER PLANTS.

Anderson, S. C.—Joseph E. Sirrine, of Greenville, has prepared plans for the electric power plant which is to be constructed at Hatton Shoals on the Tugalo River, to develop 5,000 hp. for the Hatton Shoals Company, of which R. B. Ligon, of this city, is president.

Georgetown, Col.—The Waldorf Mining & Milling Company plans extensive improvements. The purchasing of the Dryden mill site recently has brought to light the fact that the company proposes installing a complete electric power plant.

Knoxville, Tenn.—The Oliver-Stewart Company of this city has been incorporated with a capital stock of $25,000, by W. J. Oliver, of this city; A. B. Stewart, of Columbia, S. C., and George F. Parkes, of Nashville. Its purpose is to construct a power plant on the Tennessee River 30 miles from Chattanooga.

Lineville, Ala.—Messrs. Henderson, Lewis Brothers & Co., of this city, will build a cotton mill and develop a water power, to which will be connected an electric plant for transmitting the power to the proposed cotton mill and to other industries.

San Jose, Cal.—C. W. Fancher, Thomas Harris and T. B. Gambel, of this city, will erect a power plant at Yerington, Nev.

BIDS WANTED.

Freeport, Ill.—The city council will receive bids for electrically lighting this city for a term of five years.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 17⅜@17¾c.; Lake 17½@17¾c.; casting, 17@17½c.

Reports of an increase in capital of the Westinghouse Company are denied in Pittsburg.

The advance in copper metal to the highest price in five years is causing heavy purchases in the stocks of producing mines.

Control of the United Railways Company of San Francisco has passed from Brown Bros. & Co. to Ladenburg, Thalmann & Co. and associates.

There is a report that the earnings of the National Carbon Company for the present year will approach something like 8 or 10 per cent. on the common stock.

General Electric rights are being dealt in on the curb in New York. The rights are worth about $10 per share at current price of General Electric stock.

Application has been made to the New York Stock Exchange to list $4,000,000 Keystone Telephone Company of Philadelphia first mortgage 5 per cent. bonds of 1935.

Philadelphia Rapid Transit October earnings were very large, the gross showing a gain of $94,000 over the same month last year. This is an average increase of over $3,000 per day. and is the largest increase of any month this year.

Henry L. Doherty has been elected a director of the New York & Queens Electric Light & Power Company. He is connected with many lighting companies, and has been general manager of the American Light & Traction Company properties.

The time for deposit of stock of the San Francisco Gas & Electric Company and the California Gas & Electric Corporation, which are to be merged into the Pacific Gas & Electric Company, with the Union Trust Company of San Francisco, has been extended to December 1.

The Commercial National Bank of Albany, N. Y., up to the close of business Saturday, had received on deposit 94 per cent. of the capital stock of the United Traction Company, and it is expected that the entire issue will come in under the offer of purchase at $150 a share made by the Delaware & Hudson Company's interests.

The new stock of the Philadelphia Electric Company of America will make about 448,646 shares, par $10, or $4,486,465 outstanding. The company is paying 7 per cent. dividends and earned last year 10 per cent., or about $450,000 on the capital stock then issued. Allowing for the 35-cent dividend in January, the rights at the market price of 11⅜ figure a value of about $12.50 on 100 shares.

A rumor is current that a suit of some kind is threatened against the Metropolitan Street Railway and the Metropolitan Securities Companies of New York. Its character has not been revealed, but there are hints that if another assessment is called on the Metropolitan Securities Company payment of it will be enjoined. Local interests in the properties say they know nothing whatever about the matter.

The Helena (Mont.) Light & Railway Company, which took over the entire electric lighting, street railway and gas service of Helena, reports that the common and preferred stock now issued amounts to $935,000. The present issue of securities provides funds for acquiring the properties and more than $160,000 for improvements and additions. For ten months of 1905 the net earnings were $66,081, nearly $14,000 more than the annual fixed charges.

EDITORIAL NOTES.

Electric Typesetting. Though not widely discussed the electric typesetting machine is already an actuality. Its position in the field for which it is intended is being more assured every day. By this is meant that the idea of typesetting by electricity, though not entirely novel, at least represents the tendency noticeable in a great variety of directions to apply electricity to all forms of arduous labor wherever possible. The graphotype, as it is called, is an electric typesetting machine, in the sense that instead of the lead being melted by gas flame it is liquefied by passing through a metal tube heated by electricity. The matrix by which the letter is formed is made by electricity, and finally, the entire movement of the working parts is caused by the use of electric power. The suggestion implied by the use of electricity for typesetting is not to be disregarded, whether the graphotype does or does not find its place in the composing room. The history of invention clearly shows that the inventions that survive the test of time are valuable only in the respect, to use a simile, of making two blades of grass grow where only one grew before. They survive if they are able to give more in either quality or quantity of output than have been formerly obtained. The introduction of the typesetter, or typemaker and typesetter, meant the establishment of daily newspapers on an entirely new basis. It not only facilitated composition in a typographical sense, but was the positive means of developing the great newspapers. The electric typesetter thus has its work cut out for it. If time and expense are saved by its use radical changes will soon be noted in the composing rooms of the leading papers and magazines.

A Remarkable Electric Locomotive. Now that electricity is accepted on all sides as the power destined to transform our railroads, as it has our local city car lines, into a new system of propulsion, the fact that a new and most remarkable electric locomotive has been tried and tested adds to the general interest prevailing in regard to the nature of this invention. Though using the word invention in a popular sense, the better title to apply would be that of system in this instance. The idea crystallized in this case is best understood as a chain of transformations, consisting of and beginning with, first, the development of mechanical energy from the explosion of gasoline in a specially constructed engine; second, the development of electrical energy by means of a generator driven by the said gasoline engine; third, the storage of the electrical energy in batteries where it is always ready for use; fourth, the utilization of the electrical energy stored in the batteries by motors which drive the locomotive containing the apparatus. In other words, the remarkable feature of this locomotive is discovered in its method of generating power and its manner of utilizing it. The engineering world is fully agreed on this point—that the control of the movement of a vehicle by electricity is unsurpassed by any other imaginable method. They, as a whole, have fully realized the necessity for greater progress than hitherto obtained in the art of railroading. It became almost a tradition among them that the limits of steam propulsion on land have been closely approximated, and that it would mean a totally new scheme of operations that would invite better speeds and a higher economy in developing the higher phases of railroading.

To get better speeds and a higher economy is therefore the keynote to the situation. This, in addition to a less complicated form of control, seems to illustrate the features embodied in all attempts to raise the standards of traction, either as they exist in short stretches of suburban track or over the long reaches of transcontinental lines. The invention and system therefore of the new electric locomotive embodying some of these possibilities demands our attention.

It is the work of Lars Nelsen, and makes a speed of 50 miles an hour. The general superintendent of the Baltimore and Ohio Railroad and the superintendent of motive power of the Pennsylvania Railroad were among the specialists taking a ride in this substitute for the familiar form of steam locomotive. It is intended to replace the locomotive proper on all branches and spur lines, and judging from the results of a highly satisfactory test, attended by experts other than the railroad officials, this intention may be soon rapidly carried out in general practice. The apparatus employed was an 80 hp. gasoline engine driving a 50 kilowatt generator. The electricity was fed into a storage battery consisting of 103 cells, and used as required in driving the entire equipment. It is thus seen to be really a complete electrical generating and storage battery plant, whose energy is ultimately consumed, subject to the motorman's control, as in the case of any other electric car. But a locomotive must necessarily possess sufficient grip on the rails to move whatever is attached to it without stoppage. In this respect the sheer weight of the steam locomotive is a distinct advantage, but it is not a disadvantage in the case of this unique combination of parts described, for the reason that this is readily compensated for by the use of more, or at least larger, gasoline tanks. It is thus seen to be a case in which the possibility of the tractive effort, if reduced by the generating and storage battery equipment, may be adequately made up by the carriage of more liquid fuel. Pound for pound, gasoline gives out many times the available energy of coal, particularly as coal is now burnt under the boiler for steam making. The standards of economy are therefore bound to be exceeded, in spite of the fact that the energy obtained from the gasoline is passed through the engine, the generator, the storage batteries and then the driving motors. It is not at all difficult by the use of electricity to completely shatter the standards of steam engineering and establish higher ones. For this reason a gasoline electric locomotive is on its face a distinct step forward. It means a *coup de grace* in hastening the already heralded demise of steam traction.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The annual meeting of the Underwriters' National Electrical Association will be held in the rooms of the New York Board of Fire Underwriters, 32 Nassau street, to-day (December 6) at 10 A.M.

◆

Telephones connected with a transmitter on the pulpit were placed in the Munn Avenue Presbyterian Church, at East Orange, N. J., on Sunday last, to enable persons in the rear of the edifice to hear distinctly.

◆

The Bureau of Steam Engineering of the Navy Department will soon conduct an official efficiency and steam economy test of a 1,200 hp. Curtis turbine erected for demonstration purposes at the works of the Bliss Company in Brooklyn, N. Y.

◆

The American Society of Mechanical Engineers is now holding its 52d meeting in New York City. The Edison auditorium of the New York Edison Company will be the center for some of the sessions. The convention will conclude its labors on Friday.

◆

It is learned that already nearly sufficient proxies have been received by the General Electric management to carry the recommendation of the board of directors in regard to the new stock issue. It is probable that December 16 will also be fixed for closing the books for the subscription privileges to the new stock.

◆

The New York State Association of Electrical Contractors will convene in Buffalo on January 16.

◆

Lee W. De Forest, inventor of the De Forest wireless telegraph system, says the "wireless transmission of power" is not a wild dream, but a scientific possibility. "The history of wireless electricity is but a repetition of the wire system," says De Forest. "First crude signals, then intelligence conveyed over the wires, next speech and lastly power. Years ago when the first crude signals were sent over the wires it was thought that a separate wire would be needed for every character of the alphabet. I am now experimenting in my laboratory at Jersey City with wireless telephony. My work is already attaining some form. As soon as the wireless telegraphy is a little more improved I expect to bring out a system of telephoning without wires which will come into general use. After that the transmission of power through the air without wires will come. It will follow just as surely as it did in wire electricity. I am working in that general direction now. I can in a sort of way see the end of the development."

◆

At a recent mass meeting of civil, electrical, mechanical, mining, military and naval engineers in Washington, D. C., an organization was formed to be known as the Washington Society of Engineers.

◆

The Elkins-Widener Syndicate of Philadelphia, which has been negotiating for the street railways of Cleveland, O., dropped the matter on Saturday. Mayor Johnson insisted that a three-cent fare be maintained, and the syndicate decided not to buy.

◆

Lieutenant Commander S. S. Robinson, of the Bureau of Equipment of the United States Navy, with the mayors of Wilkes-Barre and Scranton, Pa., and other guests witnessed the first public test of the Murgas system of wireless telegraphy. The test was conducted between experimental stations 22 miles apart, between Wilkes-Barre and Scranton, and was successful. Every message was accurately recorded. The messages were sent by the Morse code, 45 words a minute.

◆

The 200th anniversary of the birth of Benjamin Franklin, philosopher, scientist and statesman, will be observed in Chicago, Wednesday, January 17, in connection with the electrical show. It will be known as "Ben Franklin Day" and the features will be such that will demonstrate the marvelous development in electricity, the science in which Franklin's experiments and discoveries formed a foundation for the wonders of to-day.

◆

A lecture on "Electric Heating" will be given by Mr. W. S. Hadaway, Jr., before the Electrical Engineering Society of Columbia University, New York City, in room 301, Engineering Building, this (Wednesday) evening at 8:15 o'clock.

◆

The wireless telegraph station at Manhattan Beach, N. Y., was lately in communication with the stations in both Galveston, Tex., and New Orleans, La., there being a distance of more than 1,200 miles between the stations.

ELECTRICITY IN SERVICE ON BRITISH BATTLESHIPS.

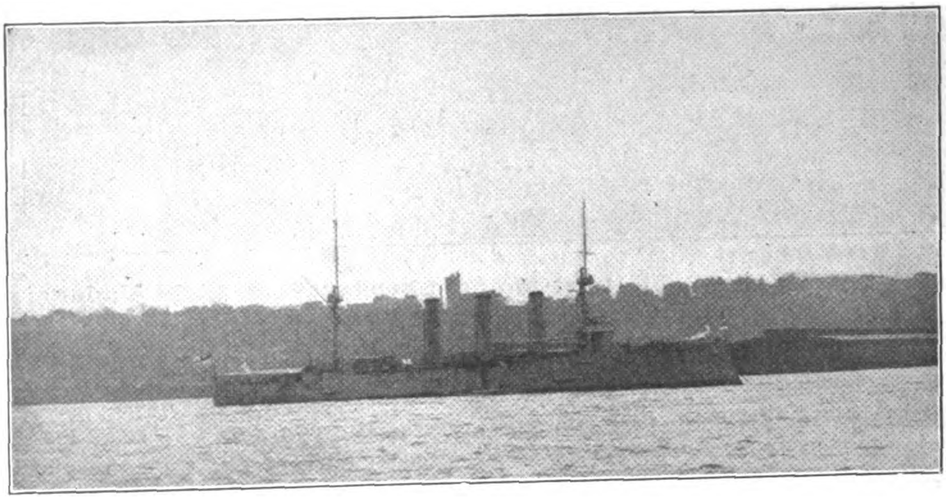
BY EDWARD NELSON.

Modern naval warfare represents the highest and best applications of electrical and mechanical devices. In many instances the apparatus does not differ in any particular detail from the same type and class used for civil purposes. But the extraordinary requirements of warfare have made it necessary to strengthen and embellish the apparatus to meet the rude shock of actual service. The modern battleship is theoretically and practically a vast fighting machine in which two forms of energy are extensively employed. The ship is propelled by steam power, but electricity is the reigning influence with regard to the lighting, the ventilating, the signaling, the adjustment of huge mechanisms, such as 13-inch guns, and the actual communication established between battleship and battleship.

The following description of the electrical apparatus found on one of the British cruisers, which recently visited New York, will cover the principal features of the mechanism employed. These cruisers represent the most modern ideas in the field of naval engineering. H. M. S. "Cornwall," from which the accompanying illustrations were obtained, was placed in commission a year ago, when war seemed imminent over the North Sea fishing tragedy.

With regard to her lighting, it may be stated that the generators employed consist of four direct-connected compound wound dynamos of 50 kilowatts apiece. The pressure they generate is carefully kept at 100 volts for reasons which relate to the naval signaling scheme. But the generators with 500 amperes capacity apiece otherwise supply their power for consumption in the lighting system, and the motor system above and below deck, and in the ventilating system.

The generators feed into a common switchboard and are attached to a pair of bus bars and an equalizing bar to absolutely preserve uniform potential under all conditions of load. Great stress is laid upon the preservation of the pressure, in fact speed indicators are attached to the dynamos whose dials are so subdivided that a difference in the revolutions per minute between one machine and another is immediately detected and remedied. The engines driving the dynamos are of the regular high speed condensing marine type, running at an average speed of 570 revolutions per minute. The main switchboard consists of a glass inclosed cabinet, the doors of which open outward. This switchboard is made of slate and has mounted upon it, measuring, protective and controlling apparatus as follows: Each generator has a main switch, a circuit breaker, ammeter, voltmeter, ground detector and lightning arrester. The rheostat controlling the shunt fields is likewise mounted conveniently at hand. A polarity indicator is employed in addition to the other apparatus, to prevent a reversal of current in any of the circuits.



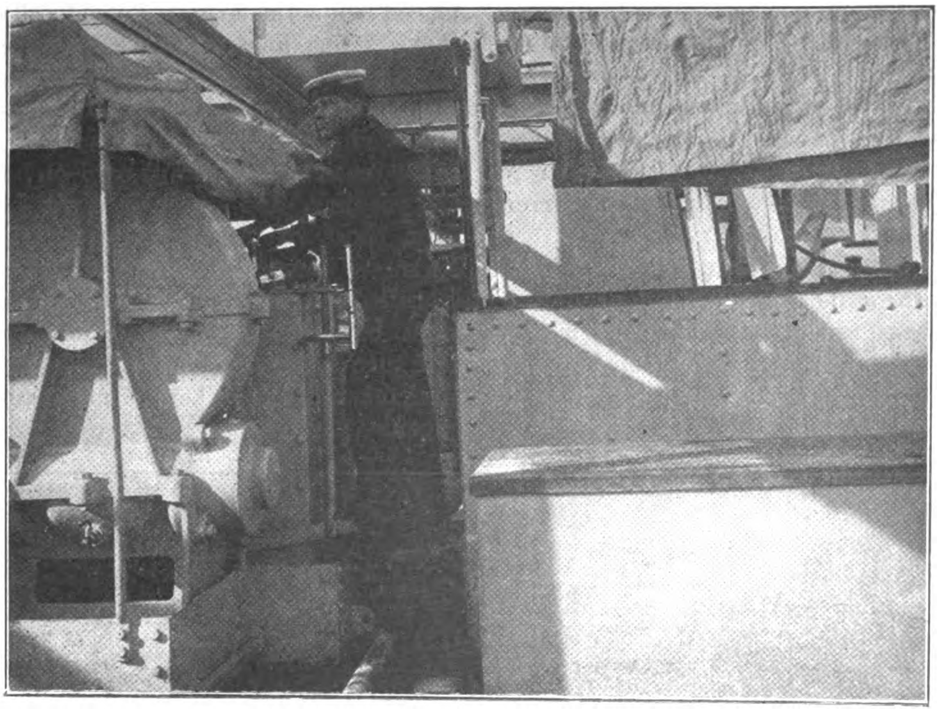
H. M. S. "Cornwall."

The generating plant is so designed that each unit can be run independent of the others, or the entire number may be thrown in multiple. Provision has been made in mounting the generators to avoid the disturbing effects of gyroscopic action. In war vessels particularly, the swift movement of the vessel is one of the purposes of its design, and it is evident that any heavy, rapidly rotating mass would tend to swivel around during such operations. In this respect both ocean liners and battleships have taken the precaution to mount all armatures parallel to the keel, thus reducing the wear on bearings, and the strain spoken of on the moving parts. The position of the dynamos is toward the middle of the vessel and mounted on a substantial bed plate, strong, though not necessarily heavy, to avoid the pitching and rolling due to the immense weight of the superstructure. In addition it may be stated, that the shock due to the impact of heavy projectiles, calls for a design and construction which will permit of operation under all conditions. It is vital in naval warfare that the lighting and signaling be carried on if an engagement occurs at night. The importance of this is accentuated by the fact that not only must there be light on board during an attack, but the movement of the heavy guns themselves is controlled by motors receiving power from this source. The position of the plant like that of the boilers is such that it it almost impossible for a shell to reach it. In fact, to gain more protection in this respect, two of the generators are placed below the armored deck, and two above, which, however, are well protected against shot and shell by steel bulkheads, and several compartments with walls of hardened steel.

The incandescent lamps used on board are peculiar, and differ in their bases from those of American manufacture. No screw bases are employed, but what is called the bayonet catch; the lamp must be pressed forward and given a half turn to engage with the detaining mechanism in the socket. During an engagement in that part of the ship subjected to the greatest vibration, the lamps are readily shattered. The powder and ammunition handling rooms and magazines, as well as other parts of the interior of the vessel during the day as well as night, are dependent upon the dynamos for their illumination. The incandescent lamp is the only solution of the lighting problem in chambers containing high explosives. A lamp must instantly give light when applied to the socket in these warships, as time is an element of the greatest importance during certain moments of action. The lamps are protected by an outer globe so that the fracture of the lamp itself invites no risk of explosion.

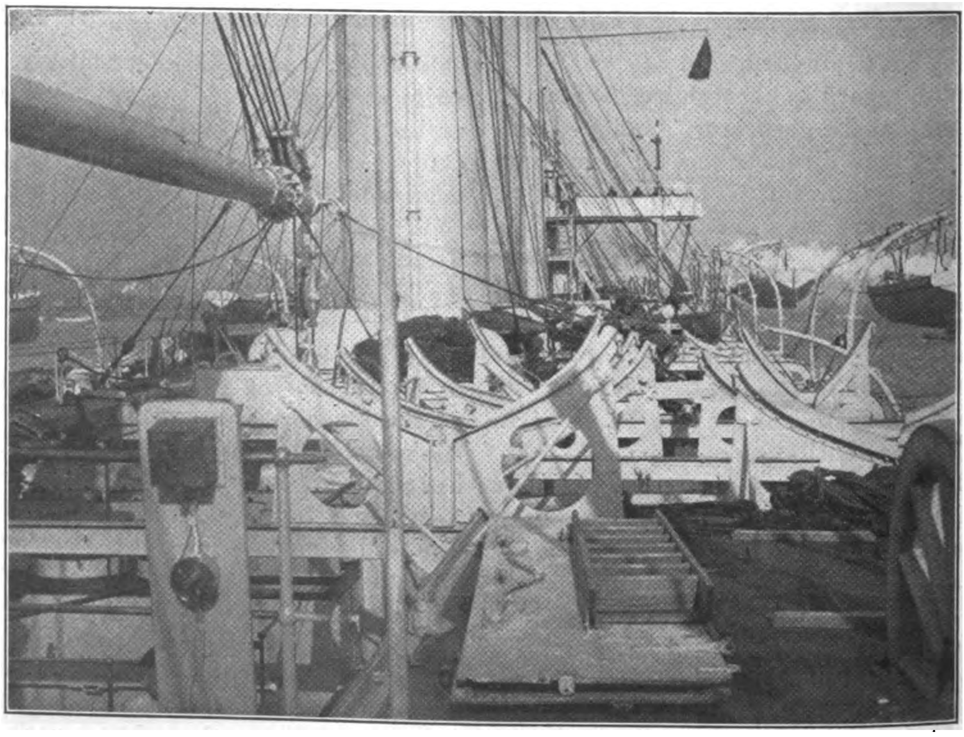
In all there are 900 incandescent lamps in use, ranging in candle power from 1 to 50, including candle powers of 5, 8, 16 and 32. The 1 cp. lamps are employed at night to illuminate the sights of the quick firing guns. In addition to the incandescents two powerful searchlights of about 100,000 cp. are used for signaling purposes and smaller searchlights for general use. The illumination of the coal bunkers during the act of coaling is accomplished by four arc lights.

To light the decks half shaded police lamps are employed, which turn the light entirely inward. The control of this system of lighting is obtained by means of waterproof switches inclosed in iron boxes. When additional illumination is necessary portable clusters are employed.



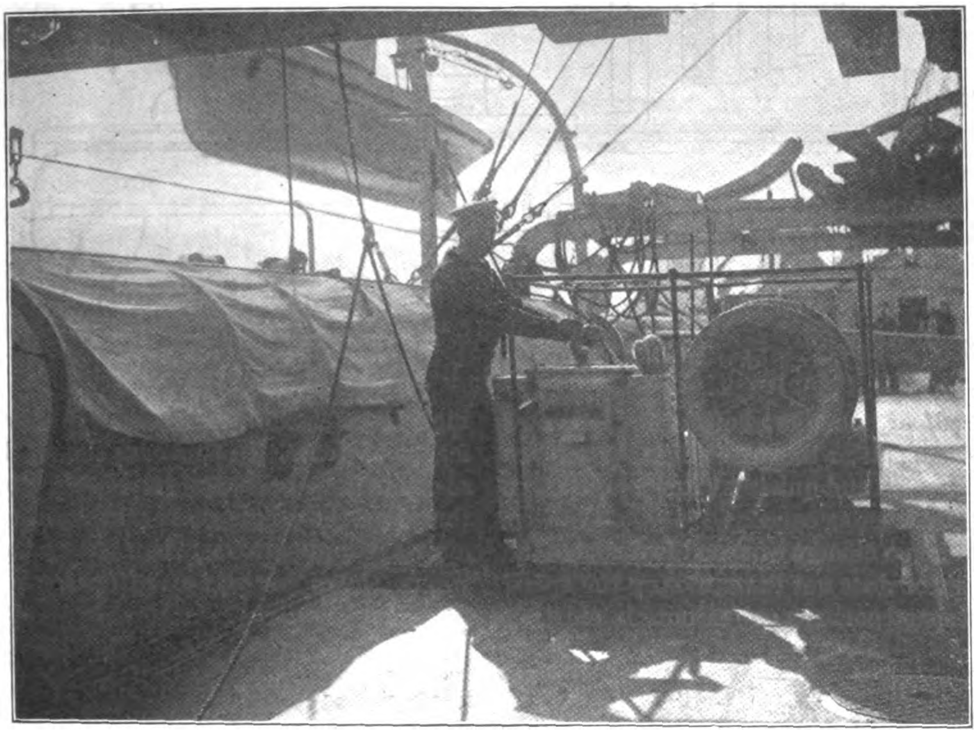
Controller for Boat Hoist Motor, Showing Pilot Light Under Right Arm of Operator.

Scattered about the deck and superstructure are a series of iron incased terminal boxes to which these portable lamps can be attached; in all there are eight, providing means for rapid temporary illumination; each box has two connecting sockets. One of the sockets is supplied with a resistance in series for the ready connection of an arc lamp. This resistance is cut out when a regular cluster light is used instead. These lights are provided with highly polished brass reflectors and the connecting wires consist of a heavily armored, flexible, waterproof, insulated cord. For night signaling a masthead flashing system is employed, which is controlled by a heavy pattern telegraph key. The lamps employed for this purpose are of 6 cp. arranged in a bank of 16.



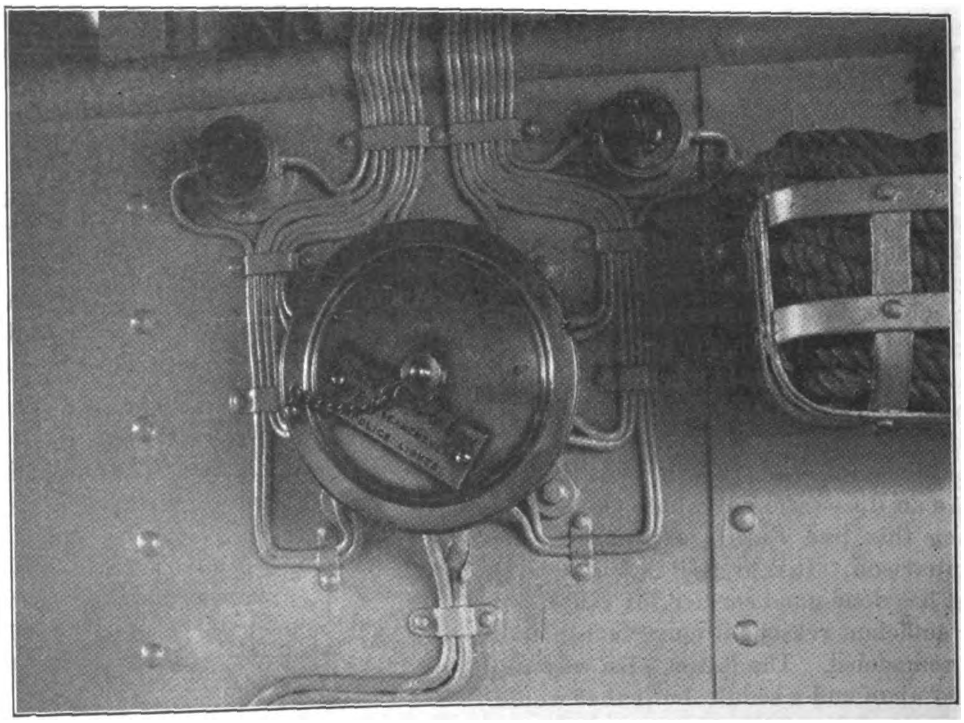
View Overlooking the Superstructure, Showing Searchlight and Semaphore on Signal Bridge.

The power equipment relates largely to the ventilation of the lower decks, control of the heavy guns in the barbettes, the handling and hoisting of ammunition, weighing the anchors, and for general hoisting purposes, including coaling. Unfortunately, owing to naval regulations, it was impossible to secure photographs of the interior of the barbettes or conning tower. But it may be stated that the guns are mounted in pairs in the barbettes on the fore and half shelter decks. The gunners have at their finger tips a pistol grip apiece. The function of this is to train the guns and at the critical moment a trigger is pulled, which acts as a circuit-closing device, ignites the powder and fires the shell. The breech of the gun contains a fuse which is ignited by current controlled by the gunner. The smaller guns are trained by hand, but fired electrically. To prevent premature ignition in the breeches of the guns safety attachments are provided, which make the firing mechanism inoperative until the breech blocks are properly closed. The ammunition supply is obtained in three different ways of an electrical character; the first is an endless chain conveyer operated electrically for the largest guns; second, an endless rope hoist for guns of less calibre, and third a a whip hoist for the quick-firing ordinance. The batteries used for ignition of the guns are contained in waterproof metal cases. The conductors leading from them are heavily insulated and protected by a braided metal armor covering of about half an inch diameter. The motors for training the guns in the barbettes are series wound, because the load they bear is constant. The extremely delicate balance of the guns makes it unnecessary to use very much power because in spite of their immense weight they can be moved by a touch of the hand. On the wall of the barbette is a switch which controls the fire of the gun. This switch is of such a character that it enables the guns to be fired either separately or simultaneously. In other words, the switch sends the current into both guns in multiple if necessary. But the overheating of a gun would mean its temporary isolation from the firing circuit and in consequence a switch which would enable it to be cut out as described. The use of electricity is shown to be the main influence in the lighting of the ship, in signaling by means of searchlights, and the handling of the ammunition, and in the movement and firing of all guns on board. The current is used for other purposes, such as the hoisting of the heavy boats, some of which weigh as much as 18 tons. This hoisting machinery consists of iron-clad fully incased waterproof multipolar motors. They are geared to winding drums, and governed by controllers which permit of six different speeds in either direction. Each motor is provided with a pilot light inclosed in a composite, heavy glass and metal hood, which indicates the condition of the circuit at that point. There are two hoists used for coaling purposes similar in design. They are of approximately 30 hp. apiece, and are capable of adjustment by the removal of hand plates held in position by screws and wedges. Steering is accomplished by means of a combined electric and compressed air equipment called a telemotor. This device is so constructed that the steering wheel must be firmly held at all times, otherwise the rudder will swing to its normal position, due to the swing of the handle. In other words, the rudder remains in a normal position when the wheel is controlled by the helmsman. The helm indicators show the angular position of the rudder, and are provided with electric lights for night work. The scale is divided in the center, and one-half is provided with a green glass dial and the other half is red. The circuits are so arranged that when the rudder is turned to port, that half of the indicating scale is illuminated; and when to starboard the corresponding half is brightly lit. There are four steering wheels occupying the following positions: The first is on the signal bridge, which is the normal position of the navigating officer. In case of an engagement, this position would be vacated and the control of the ship directed from the conning tower, the second position. The two other positions are below the armored deck, a location comparatively safe under all conditions. The log in the fore chart house is read by means of an electric indicator which connects with the regular registering device at the stern.



Electric Motor Coal Hoist.

The telephone is used extensively throughout the vessel, in fact to such a degree that a central station is necessary to facilitate the transmission of messages. This station is situated in the conning tower, and communication is readily established between it and and all the heavy gun positions, the signal bridge and engine room.



Watertight Distributing Box and Switches, Showing Method of Wiring.

One important electrical equipment, in addition to the telephone system, is the wireless telegraph apparatus in use. This is located on the after bridge, but is in direct communication with the fore bridge by means of a telephone circuit.

Examination of the data presented will readily show that the control of the vessel for navigating and naval purposes is centered near the bridge, from which orders can be given by the commanding officer and readily transmitted. The general conditions prevailing at sea are such that the fewer wires employed the better the service obtained. In many parts of steel vessels a single wire is run, the hull providing a return. All conductors exposed to the salt air are heavily protected and armored. In spite of this precaution many faults develop in the course of a trip. To obviate this difficulty a very complete testing system is employed, represented by a corps of able electricians. Their duties consist of a series of daily tests of every line and circuit on the ship, whether relating to light and power or signaling. The testing equipments consist of high grade galvanometers, bridges, milliameters and millivoltmeters. The ammeters and voltmeters on the switchboard are of the Weston type, American manufacture, but the majority of the other apparatus for measuring or testing is typically English in construction.

◆

Lake Titicaca, the highest navigable lake in the world, is to be tapped for electric power to run the Peruvian railroads and to supply a surplus sufficient, it is believed, to enable Peru to take a promnent place among the manufacturing countries.

ELECTRIC MOTORS IN THE MACHINE SHOP.

BY W. H. WAKEMAN.

ARTICLE I.

While there are many places in which electric motors are the favorite means for transmitting power, they give special satisfaction in machine shops, or where machine tools are built, requiring the use of lathes, planers, drill presses, etc.

The material used in these shops is not only heavy but bulky also, requiring much space for the operation of working it into the finished product; therefore where power is transmitted by belts the friction load is frequently from 50 to 60 per cent. of the average load, and in one case in which the writer made a careful test it exceeded the latter figures by about 5 per cent.

This unprofitable condition of affairs was due to the fact that when a lathe or a planer was wanted it was set up there without regard to the difficulty of transmitting power to it. A line of shafting with brood pulleys of small diameter was run to some point near the above-mentioned machine, a countershaft was put up over it, belts were laced and work soon commenced.

This shop has a wide reputation among users of machine tools and has enabled those interested to make money in the past, but times have changed and every effort must be made to reduce cost of production and turn out better work now.

Here is one case where the electric motor is superior to other means of driving a machine, as it requires no line or countershafting. The next problem to be solved in such a case is whether to equip the old machine with motors, or sell them and buy new ones with motors already mounted on them.

As an illustration of what can be done along this line Fig. 1 is presented for comparison. It represents a belted lathe that has done good service for years, but for sufficient reasons it must be replaced or remodeled. The latter plan was decided upon and a saddle built that would rest upon two spindle bearings, and thus support a motor for driving it.

Fig. 2 is the same machine with a motor in place ready for work. The difference in power required to run this lathe would not warrant the change, but when we know that now there are ten times as many speeds available as formerly, it becomes plain that a greater variety of work can be done and much more produced per hour than before, for it is now an easy matter to run at high speeds for light work and quickly change to slower speeds when necessary.

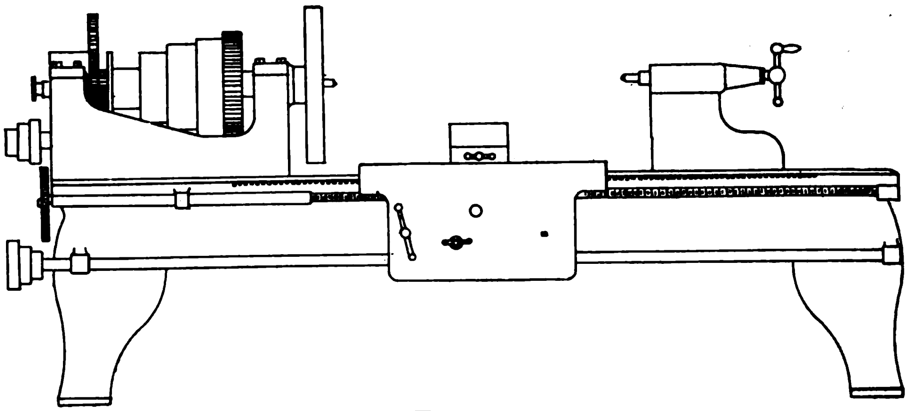


FIG. 1.

When a change of speed is desired the operator does not have to stop the speed and spend perhaps one minute in shifting the belt, as he controls the speed by a suitable device located in the apron of the lathe.

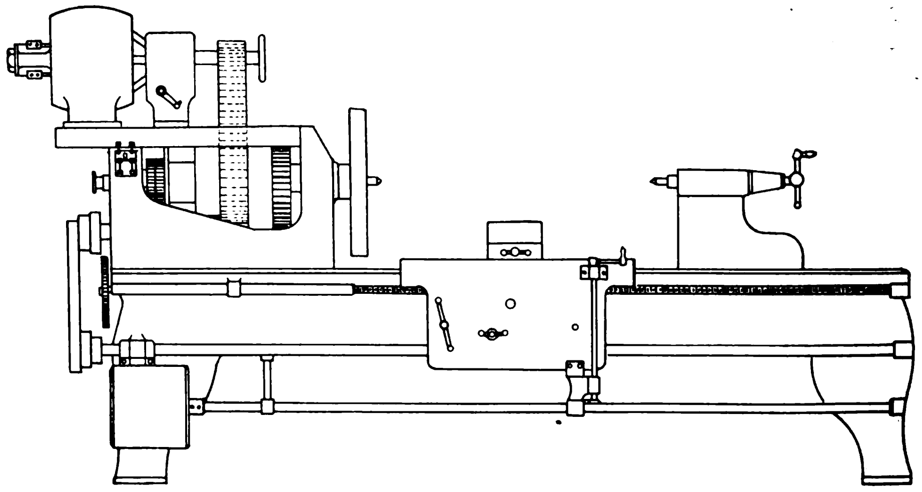

FIG. 2.

A split gear was clamped on the second step of the cone pulley and driven by a silent flat chain, making a positive drive at all times. This is much superior to a belt, which would surely be troublesome on account of the short distance between driving centers.

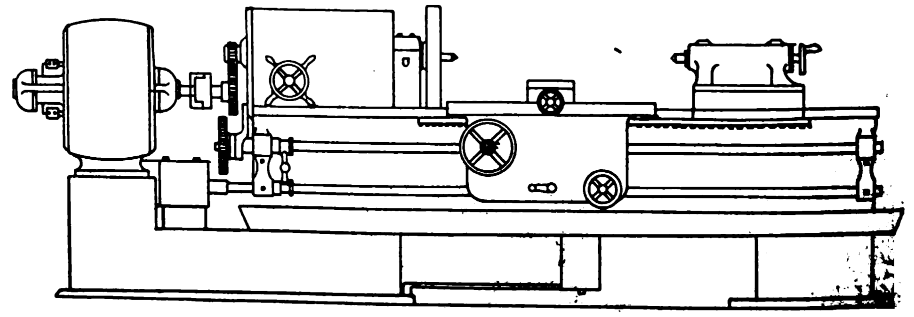

FIG. 3.

There are other tools to which motors may be applied with profit, and this illustration is given to demonstrate the possibilities along this line.

Fig. 3 illustrates a Lodge & Shipley high speed lathe driven by a motor by means of gears. In this case the machine seems to have been designed for a motor, therefore the whole presents a more symmetrical appearance than is possible where the motor was an after consideration.

In order to take advantage of the highest speed possible on light work it is necessary for a motor to be designed for great and sudden changes in speed. It is generally understood that the speed of motors is frequently changed by providing a rheostat that presents great resistance to the flow of current when only a small amount is wanted to drive a machine slowly, thus wasting energy, but this defect is much modified in the latest improved motors for the service above described.

Fig. 4 illustrates an inclosed motor driving a pair of shears for quickly cutting off iron bars to any required length in places where they are used in large quantities. The shaft to which the motor is directly connected also carries a heavy balance wheel that assists greatly in maintaining a uniform speed under great and sudden changes in load. When a bar of iron is to be cut off the shears must do their work by a sudden short movement of the cutting edges, which would quickly check the speed were it not for the balance wheel, but before its momentum is absorbed by the resistance offered the bar is cut off and the machine is running light again.

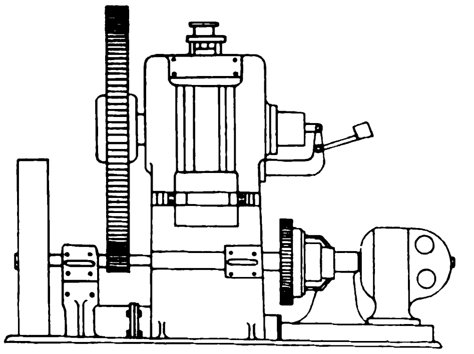

Fig. 4.

Fig. 5 represents one of the neatest applications of a motor that I have ever seen. It represents a grinder with an emery wheel on each end and an inclosed motor in the middle. As it is wired from under the floor there is nothing to indicate that it is anything but a self-propelled machine, so neat and clean is its appearance.

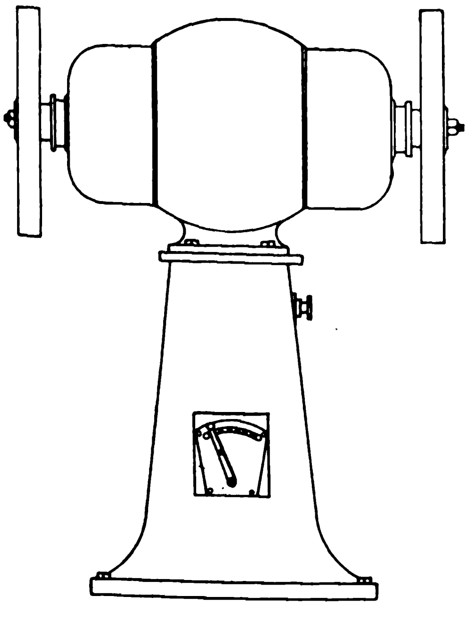

Fig. 5.

If an ordinary grinder was driven from a countershaft in the room below, and the belt came up through the hollow base where it could not be seen in the machine room, it would compare favorably with this type, but I have never seen one fitted up in this way. If it should be attempted it would be difficult to arrange a belt shipper that could be worked quickly and easily. It is generally driven from overhead, bringing the belt very much in the way when certain kinds of work are to be done. As it is possible to get different speeds to suit various sizes of emery wheels and for adaptation to work required, this becomes a valuable feature worthy of careful consideration.

LIGHT, HEAT AND POWER PRINCIPLES.—XI.

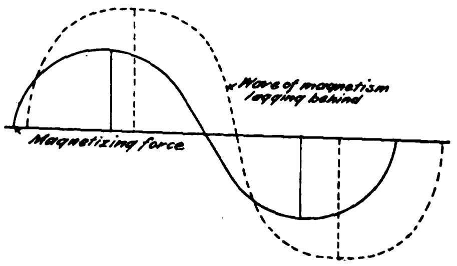
BY NEWTON HARRISON, E. E.

Weight of Transformer Iron and Losses.—All alternating current apparatus makes use of sufficient iron to constitute an item of great loss when the entire weight is considered in connection with the loss of power such weight represents. Although an old table, the following figures obtained from experimental data supplied by Prof. Ewing and used by Gisbert Kapp, can be referred to for the purpose of finding out the number of watts wasted per ton of iron and in consequence the horse power dissipated per ton as well:

Lines of force per square centimeter in the iron.	Watts wasted per ton of iron.	Horse power wasted per ton of iron.	Lines of force per square inch.
2,000	650	.87	12,500
3,000	1,100	1.48	18,750
4,000	1,650	2.21	25,000
5,000	2,250	3.02	31,250
6,000	2,900	3.89	37,500
7,000	3,750	5.03	43,750
8,000	4,450	5.97	50,000
9,000	5,550	7.43	56,250
10,000	6,650	8.90	62,500

It is not an unusual thing for central stations to have from 20 to 100 or more transformers attached to their circuits, weighing on an average of from 100 to 500 pounds or over, according to their capacity. This being the case, if the figures given are taken to represent the weight of iron, it is evident that 100 transformers with 100 pounds of iron apiece would weigh 10,000 pounds or five tons. At an average induction of 7,000 lines of force per square centimeter, or over 40,000 per square inch, the loss of power per ton would be about 5 hp. For 5 tons of iron the total becomes 5 × 5 = 25 hp.; quite an expensive item if calculated annually at the rate of $50 per annum per horse power, thus meaning a fixed loss of 25 × $50 = $1,250. In some central stations, supplying considerable electricity over scattered sections of a town or city, the number of customers may be so great that several thousand transformers are in use at once. At an average of only 50 pounds of iron apiece, 1,000 transformers would represent a total iron weight of 50 × 1,000 = 50,000 pounds or 25 tons. At the same rate per square inch for the lines of force the loss per ton of iron is 5 hp. This means a total annual loss of 5 × 25 = 125 hp., which costing $50 per annum, would mean a net loss of $6,250 a year. The loss of power in the primary and secondary coils is not considered in this estimate, but it would mount up as well to important figures. Though a great saving in copper is made in the transmission and distribution of electricity by means of a high pressure alternating current, a balance can only be properly struck if the iron losses and individual losses in the copper of each transformer are carefully considered.

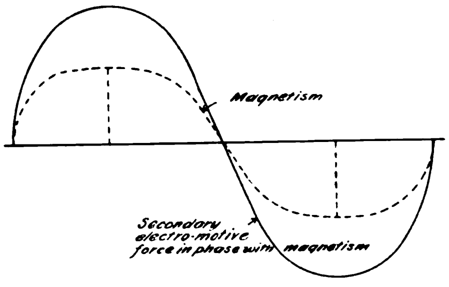
Lag of the Magnetism Behind the Magnetizing Force.—The application of a magnetizing force to the iron is not sufficient to instantly magnetize it. A certain interval of time elapses before the lines of force appear in response to the magnetizing force. Hysteresis causes this lag of the magnetism behind the magnetizing force. The result, therefore, of a magnetizing force applied to a piece of iron would be a magnetization curve a little behind the ampere turns creating the magnetism. The magnetizing force naturally follows the sine wave, for the obvious reason that the current and pressure are developed as sine waves. The magnetizing force simply consists of the coil turns and the current; it therefore rises and falls as a typical sine wave as well. But the magnetism will not develop in this manner; its growth and diminution are formed in the hysteresis curves, with the difference, however, that when the change occurs slowly the curve is of a square flat type, as shown in the illustration. It is also evident that the magnetism lags behind the electrical energy as found in the magnetic curve where it crosses the zero line to a degree



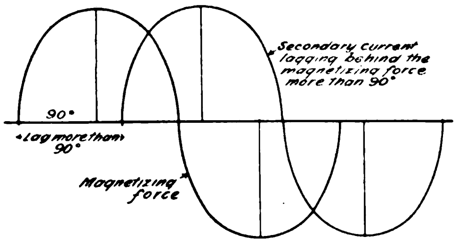
Relationship of the magnetizing force and magnetism.

dependent upon the responsiveness of the iron to slow or fast changes.

Influence of the Magnetism Upon the Secondary Coil.—The magnetism in the iron is the cause of the secondary developing its EMF. It is evident that the secondary EMF. is in perfect phase with the magnetism of the iron core. The degree of change represented by the rising and falling curve of magnetism is therefore an exact measure of the degree of change developed in the secondary coil in the way of electromotive force. The reason for this is found in the well-known fact that lines of force and turns which vary according to simple principles produce EMF. In this case the lines of force vary, but not as rapidly as the magnetizing force producing them vary. The coinciding of the rise and fall of the secondary EMF. with the rise and fall of the magnetism does not mean a current in the secondary which is in phase with its EMF. If the magnetizing force be plotted with its resulting EMF. in the secondary, and then the secondary EMF. be plotted with the current in the secondary, a greater difference of phase will naturally be found between the magnetizing force and the secondary current than can be explained by any other means than that of hysteresis.

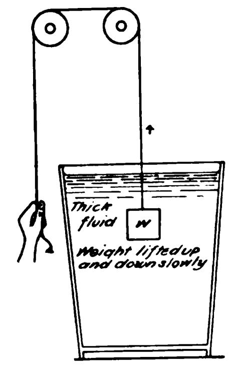


Relationship of the magnetism and the secondary EMF.

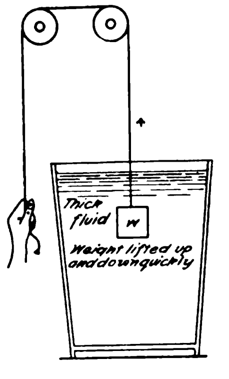


Relationship of the magnetizing force and the secondary current.

The Two Causes of Hysteresis.—From a physical standpoint hysteresis may be regarded as dependent in its manifestations upon two things: First, the degree of magnetization to which the iron is affected when the magnetizing force is applied to it; and second, the rate at which the magnetizing force is applied, withdrawn and reversed. This has been described under the title of static and viscous hysteresis by comparing it with a weight drawn up and down through a thick gelatinous fluid. To quote: "Apart from the fluid resistance, the work done in lifting the weight against gravity, say 100 times, is 100 times the work required to lift it once; but if fluid resistance comes into play, and if this varies as the square of the velocity of the moving body, then the total work done in lifting the weight through the fluid will be dependent also upon the rate at which the cycle is performed."



Simile to hysteresis with a low rate of reversal and strong field.



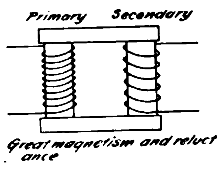
Simile to hysteresis with a high rate of reversal and strong field.

Transformer Efficiencies.—When the transformer is unloaded, that is, when the resistance of the secondary is that of an open circuit, the amount of energy wasted in the transformer is given by a formula as follows:

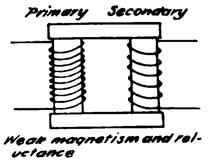
Waste of power =

$$\frac{1}{2} \times B^2 \times R_D \times \left(\frac{K}{4 \times \pi \times T_D}\right)^2,$$

where B = the lines of force per square centimeter in the core, R the resistance of the primary coil, K the magnetic reluctance (equal to $l \div \mu \times q$, where l = the length in centimeters, μ = the permeability of the iron and q = the cross-section in square centimeters), T_D = the turns of the primary coil, and π the value 3.1416. As this waste of energy is calculated from absolute units the results would be ergs, 10,000,000 of which are equal to 1 watt. The answer therefore divided by 10^7 will give watts, or if further divided by 746 will give horse power. It is evident from an examination of the formula that as the magnetization of the iron of the transformer increases the loss increases as its square. The lesson to be learned from this is that the transformer must be designed to operate at a low magnetization, when the lamps connected to the secondary are not in use. The other point of perhaps greater importanee is that the energy wasted is proportional to the square of the magnetic reluctance K. The less the reluctance therefore the less the value of the square of its value as indicated, and the less the watts wasted when the secondary is on open circuit. The expression is valuable, in showing how a transformer with iron too well magnetized will be the means of dissipating a great deal of power. A feature in transformer construction is therefore the necessary bulkiness of them in order to obtain efficiency. A low rate of magnetization and the best quality of iron are to be considered as dominating principles.



Efficiency low.



Efficiency high.

Construction of Modern Transformers for Light and Power.—The transformers manufactured for practical use in the field of light, heat and power are so constructed that their efficiencies vary with the load as follows:

1. Efficiencies of a 150 kw. transformer of an EMF. of 500 to 15,000 volts and alternations of 7,200 per minute at different points of load.

Full load efficiency = 97.5 per cent.
¾ " " = 97.4 " "
½ " " = 97.0 " "
¼ " " = 94.9 " "

Other items of information: Regulation with a non-inductive load is to within 1.5 per cent. With a load having a .9 power factor the regulation is to within 3.5 per cent.

2. Efficiencies of a 375 kw. transformer of an EMF. of 500 to 15,000 volts and 7,200 alternations per minute, at different points of load.

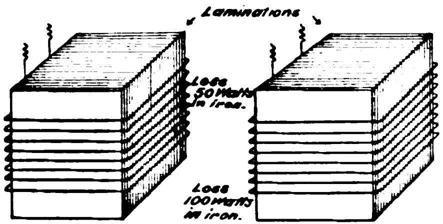
Full load efficiency = 98 per cent.
¾ " " = 98 " "
½ " " = 96.6 " "
¼ " " = 96.1 " "

Other items of information: Regulation with a non-inductive load 1.4 per cent. Load having a .9 factor 3.3 per cent. regulation.

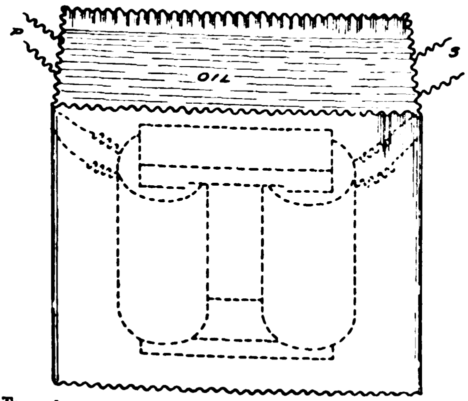
The primary and secondary coils are divided into a series of smaller coils, but of great depth of winding apiece. The insulation of each coil is complete and distinct from its neighbor, whereby the following advantages are secured by such construction:

First, it divides the total EMF. between several coils, reducing proportionately the strain within an individual coil; second, it divides the EMF. in a single coil between many layers, thus reducing the potential between adjacent layers; third, it enables the coils to be spread apart at the ends, so that a very large surface is exposed to the oil used as an insulator and cooling medium; it also provides ample radiating facilities besides thoroughly insulating the bent part of the coils; fourth, the transformer regulation is greatly improved; fifth, the winding may be readily connected in series or multiple, thus giving a wide range in EMF.; sixth, in case of damage to a coil another one may be substituted with little trouble and without it being necessary to return the transformer to its manufacturers.

The Aging of Transformer Iron.—A peculiar condition of affairs results from the aging of transformer iron. According to the records of one of the largest manufacturers in the country as quoted "It is not sufficient that the loss in a transformer be low when installed, for as is now generally known, much of the iron that has been used in transformers when subjected to the conditions prevailing in continued service is subject to a material deterioration, more or less rapid, with the result of a corresponding material increase in the iron losses. In some cases this increase has amounted to a doubling of the loss found in the transformer when first installed." The importance of this statement cannot be overestimated, because it is evident that a careful examination of the iron, from whatever source it may come, is absolutely necessary before it is used for transformer construction. It is therefore necessary to use all means that science can employ to select iron, which, though no better than that of other lots so far as permeability, coerciveness, etc., is concerned, is still superior, in that it does not deteriorate because of an inherently stable character when in practical use.



Comparative loss in iron through hysteresis when newly in service and when aged.



Transformer placed in a corrugated oil-filled case for insulation and cooling.

Cooling of the Transformer.—Corrugated exteriors are made to provide a greater surface and thus cool the contents of the transformer more rapidly. The transformer proper is placed in a cast-iron box which is filled with oil. The outside of the box is ribbed to facilitate the radiation of heat, or otherwise enlarged by means of corrugations, etc. The oil acts as a conductor in transferring the heat to the outside of the containing cases. The additional feature is that of connecting the outside of the case to a water circulating system to further facilitate its rapid cooling.

◆

COST OF FREIGHT BY ELECTRIC HAULAGE.

BY GEORGE E. WALSH.

The rapid extension of electric railways in the agricultural districts, and the construction of high-speed railways between large towns and cities, has brought the problem of handling freight by trolley into the foreground. The effort to develop the freight haulage side of electric railways has met with many obstacles, both from legislation and hostility of steam railroad companies, but fortunately most of these difficulties are being solved, and the legitimate field of operation in this respect is being exploited. The possibilities of developing agricultural and rural districts by handling freight by electric lines are fully recognized by most companies, and many owners of suburban property are anxious to co-operate with the railway companies in improving their freight handling facilities.

In the Eastern and Middle States it may, therefore, be said that a complete change of opinion regarding the handling of freight by electric lines has been brought about in the past year or two. Before 1900 the hostility to the roads was general. Municipalities refused to grant franchises to the railway lines permitting them to handle freight, and State legislators strictly opposed any attempt to amend charters that increased the rights of the electric lines. The steam railroad companies steadily refused to make any traffic agreement with the electric lines. In some instances this was so radical that important business was lost. Where electric railway feeders helped to increase the traffic of the steam roads the latter refused absolutely to receive freight direct when delivered by the former.

Such hostility could not continue indefinitely. Gradually the steam roads are facing the problem frankly, and freight traffic arrangements are being made in the East with electric lines which are not openly competing with them on parallel lines. Looked upon as feeders the electric roads are accepted as friendly corporations and the trunk lines make provisional agreements to handle freight delivered to them. Likewise State legislation is growing less hostile, and charters are being granted to lines operated by electricity to act as freight carriers in addition to their regular passenger work. Towns and cities instead of refusing the rights of their streets for electric freight haulage are more and more inclined to recognize that under certain restrictions this is a great benefit instead of a detriment to the municipality's growth. The rapid growth of interurban electric lines has demonstrated the superiority of electric freight and express traffic for certain lines of goods, and to-day where such service is in existence business is greatly improved.

There is certain bulky freight which may never prove profitable or desirable for electric railway carriage. Such heavy, bulky freight is the legitimate traffic of the steam roads even where electric lines parallel the former. This is well illustrated in the work of the several freight-carrying interurban roads in New York State. The freight traffic carried on the Albany, Rochester and Hudson Valley interurban electric lines has steadily increased in the past few years, but it is composed chiefly of small packages and merchandise rather than of heavy freight.

Express freight in particular has adapted itself to the interurban electric lines. Such freight can be carried cheaper and with much greater dispatch by the electric roads than by the steam. By virtue of their right to use the city streets, the express freight can be delivered nearer the consumer than it will ever be possible for the steam roads. Frequent delivery stations along the route of the electric roads in the city make it very simple to handle express expeditiously. The express freight business in 1903 reached considerable proportions in the East. The Hudson Valley Electric Railway carried upward of $22,190 worth of express matter that year some 54,842 car miles, making an average of receipts per car mile of 40 cents. Since then this traffic has just about doubled. Prior to that there was little accommodation for local freight traffic between the towns and villages tapped by the road. The charges are considered by all shippers much less than averaged by steam lines, while the accommodations have greatly stimulated suburban growth and development. A number of plants dealing in small articles have since decided to locate along the line of this railway simply through the accommodations obtained in handling goods.

A similar story can be related of the Albany, Rochester and Newburgh lines. The latter is the smallest of the three, but it carried in 1903, the sum of $12,881 worth of freight and express packages over 16,516 car miles. The receipts per car mile amounted to 78 cents. This line runs through a farming region, and has few large villages anywhere along its route, and it must therefore depend more upon freight than upon express packages. Since its construction, the country has steadily developed, and farmers have been induced more and more to ship their produce by it. Formerly, milk, fruits and vegetables intended for Newburgh and New York City were carted over many miles of rough country road to the steam lines, and often produce was lost through lack of facilities for handling it. Anything except heavy farming, such as grain, hay and produce that would keep indefinitely, was not attempted by the farmers five miles back from the city of Newburgh.

To-day all of this has changed along the line of the electric railway. Eggs, milk, poultry and choice fruits and vegetables are raised on scores of farms, which were formerly considered useless for this work, owing to the distance from market and steam roads, and new profitable farming industries are steadily increasing. The farmers are depending more and more upon the electric railway to ship their produce to market. Only very heavy, bulky goods are carted by the wagons, and the railway has recently been considering arrangements to handle even such goods as hay, grain and winter potatoes, apples and cabbages.

With the electric railways the cost of transportation of farm produce is largely a matter of meeting certain fixed charges and operating expenses. With the railroads, and especially the small, short-haul lines, the transportation charges are often the result of years of habit without any consideration of existing conditions. Instead of developing agricultural regions within a radius of 5 to 20 miles of a large city, extortionate steam road charges tend to reduce production and give the distant competitor more advantages. The electric railways running between cities and towns endeavor to develop the agricultural possibilities of their territory to increase the local freight traffic. Farm products are thus more evenly distributed, and are not all shipped in bulk to one great market where over-supply and congestion causes loss to the producer. It is commonly claimed that fresh farm products are more difficult to secure, and at higher rates, in the small village and town in the heart of agricultural regions than in the large cities. This is due to the efforts of the steam roads to carry products over the longest possible distance. The local interurban tends to correct this, and to supply markets along its route, charging transportation rates according to the number of miles carried.

Up to date the electric railways have not entered to any extent into the coal carrying business. Under present conditions the steam roads refuse to transfer their coal cars to the electric lines, but this will not last long. The Eastern steam roads are building their own electric lines, which will naturally handle loaded coal cars. It is then a short step to general transfer of coal cars from one electric line to another. Statistics show that the prohibitive cost of coal to-day in many inland districts is due almost entirely to the fact that breaking bulk adds enormously to the price. The long cartage over country roads, furthermore, makes coal as a winter fuel a pretty expensive luxury. There are electric railways to-day equipped for distributing this important commodity without any of the present disadvantages of breaking bulk. Not until the steam roads either change their policy or buy up intersecting electric lines will this problem be properly solved.

Last year the Altoona & Logan Valley Electric Railway carried upward of $35,000 worth of freight and express goods, and the Lehigh Traction nearly $40,000. Two other Pennsylvania roads, the Lancaster and Harrisburg Traction, nearly equalled these in their freight handling. These lines run through both mining and agricultural regions. The products of the mines are practically controlled by the large steam roads, and very little of this class of freight was handled by the electric lines. An examination of the goods, however, show that many new industries only indirectly connected with mining have sprung up along the lines, which have added greatly to the business. Mine products always show an enormous waste, but their cost of transportation to manufacturing regions, makes it impossible to utilize them. A number of concerns interested in chemical and electro-metallurgical work have located near the Pennsylvania mines in the past few years, and their products form quite a considerable bulk of traffic for the electric lines. It is a question whether they would have located there had not electric railways proved accommodating and comparatively cheap in handling freight as well as passengers.

According to present rates of charges by the steam railroads the electric lines could make large profits. Most of the electric lines in the East, however, charge much lower rates even when not competing openly with parallel steam roads. Thus on most of the short steam lines in the East the average gross freight receipts are $650 per mile of track per annum, although in many cases this runs up to $2,000 to $5,000 of gross freight earnings per mile of track per annum, according to the location and nature of the freight handled. An electric railway earning this amount per mile for freight would certainly pay huge dividends upon its stock.

The question of developing the freight and express service of electric railways is now receiving the attention of the best managers and operators in the country. Heretofore the roads engaged in this business have depended chiefly upon the freight produced and consumed along their routes, but the effort is being made to handle through trade between cities in bulk. A good deal of the freight transferred from the steam to the electric roads without breaking bulk would greatly benefit consumers and shippers. The steam roads in a few of the large cities have begun to recognize this fact, and several contracts are now in effect which permit the electric roads to take freight in bulk direct from steam roads' terminals. The Brooklyn Heights Electric Railroad two years ago handled upward of $75,000 worth of freight and express, and the present year has found the Brooklyn Rapid Transit and the Metropolitan traction lines fully equipped for freight and express service. These two systems have handled more express freight the past year than any two of the large express companies combined for local delivery. This end of the service has also proved one of the most profitable. The express cars reach every freight depot in the city, and, receiving the express goods direct, distribution is rapid and satisfactory. Besides facilitating delivery of express goods, the electric delivery cars greatly reduce the amount of trucking on the city streets.

The paralleling of most steam roads by trolley lines in the East, and the effort of the latter to secure freight as well as passenger traffic, have caused not a little friction, but wiser methods than rate wars may in time prevail. A discrimination between the character of the two roads is already bringing about a healthier tone. As the steam roads are better able to carry long-distance passengers, so in the freight service they have the facilities for carrying heavy and through freight traffic which the average electric line does not possess. There can be no present competition in these two distinct lines. The electric roads are not provided with expensive freight terminal facilities for handling heavy traffic, but they are equipped for quick delivery and distribution of light and costly merchandise packages. It would be much to the advantage of the railroads to recognize this fact and co-operate with the electric lines for handling light express packages and higher class merchandise. Rapidity of delivery of such goods tends to increase business and stimulate traffic, and this can best be accomplished by the electric lines which have the right of way in the city streets.

Likewise short suburban delivery is the particular field of the electric lines. Here it is impossible for the steam roads to offer any opposition. The day of the slow wagon delivery in the suburban and country districts is past. The distribution of goods to the different small villages along the electric railway's route is a matter of simple business shrewdness. The steam railroads have to some extent recognized the fact that high-class merchandise freight can be handled easier and cheaper by electricity than by steam, and they have started to equip many short lines and feeders with electricity for this work. The development of the electrical short haul and light express service in connection with several of the Eastern trunk lines is thus quite phenomenal, and the future extent to which the service will go is beyond present prediction.

Right of Electric Companies to Condemn Land.

At Utica, N. Y., Supreme Court Justice Maurice L. Wright rendered a decision upholding the constitutionality of the law which gives to electric light and power companies the right to condemn lands which may be required in the attempts to furnish municipalities with light and power. The East Creek Electric Light and Power Company sought to acquire the lands of Norman Loucks and asked for the appointment of a commission to assess the damages. Loucks resisted, and attacked the constitutionality of the statute. Justice Wright holds that the Legislature has the power to invest in companies providing the municipalities with a supply of electricity for power and lighting the same rights that are held by companies engaged in furnishing cities and towns with water.

Whew! $150,000,000 Is All the Bell Company Needs Just Now To "Expand!"

The American Telephone & Telegraph Company (Bell), in order to secure additional capital necessary "in the large expansion of its business," contemplates the issue of $150,000,000 convertible bonds, such bonds to be sold from time to time as the needs of the concern may require. A special meeting of the stockholders has been called for December 21 at which they will be requested to vote upon the acceptance of the scheme.

How is $150,000,000 for high-water-mark? Evidently "somebody is frightened."

An Electrician Wanted.

The United States Civil Service Commission announces an examination on January 3, 1906, to secure eligibles from which to make certification to fill a vacancy in the position of electrician, at $1,000 per annum, in the quartermaster's department at large, Vancouver's Barracks, Wash., and vacancies as they may occur in any branch of the service requiring similar qualifications.

New York's Electrical Show.

At the electrical show, to be held in Madison Square Garden, New York City, from December 12 to 23, about every kind of electrical device in use up to date will be shown. There will be a model of the Williamsburg Bridge showing how Commissioner Woodbury burns waste and rubbish in an electrical incinerator and lights the bridge thereby. In the center of the Garden a "theaterphone" is to be rigged, and wires from it will be strung to the stages of various theaters. Visitors at the show will be enabled thereby to hear what is going on at the theaters.

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until December 19 for furnishing Eastern Navy Yards with the following electrical material: Schedule 260, arc lamp carbons and globes, rubber-covered wire, conduit and fittings, tape, sockets, switches, lamp cord and miscellaneous electrical supplies; schedule 261, buzzers, wire, annunciator drops, conduit fittings, miscellaneous supplies; schedule 623, motor generator set. Blank proposals can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington.

ELECTRICAL PATENT RECORD

LETTERS PATENT ISSUED NOV. 28, 1905

Electric Railways and Appliances.

805,568. Trolley-Base. Henry R. Lockhart, Westmount, Canada. Filed July 23, 1904.

805,572. Trolley-Wheel. Alexander H. Mathesius, Brooklyn, N. Y. Filed May 24, 1900.

805,827. Railroad Signal-Circuit. Eugene W. Vogel, Chicago, Ill., assignor to the Railroad Supply Company. Filed Sept. 20, 1901.

806,035. Electric Signaling and Electropneumatic Train-Control System. John A. Whyte, Toronto, Canada. Filed Sept. 2, 1904.

Electric Lights and Appliances.

805,574. Electric Gas-Lighter. Joseph Mlada, Manitowoc, Wis. Filed March 21, 1905.

Electrical Machinery and Apparatus.

805,499. Electric Drill. Stephen D. Stoycheff, Toledo, O. Filed June 26, 1903.

805,505. Automatic Regulator for Electric Circuits. Montgomery Waddell, New York City. Filed June 28, 1904.

805,509. Electric Cut-out. Willes P. Wright, Blandinsville, Ill. Filed June 13, 1904.

805,547. Armature for Electrical Machines. William T. Hensley, Boundbrook, N. J. Filed March 25, 1905.

805,725. Controlling Device for Electric Generators. Moritz von Hoor, Friedrich Reinitz and Leopold Stark, Budapest, Austria-Hungary. Filed April 17, 1901.

805,748. Speed-Regulator for Power Transmission. Charles Pfanschmidt, Chicago, Ill., assignor to the Vibrassage Company, same place. Filed May 3, 1905.

805,952. Electrical Muscular Exercising Machine. Robert O. Hammond, Buffalo, N. Y., assignor to Josiah S. Andrews, same place. Filed May 23, 1905.

Telephones and Telephone Apparatus

805,901. Telephone Exchange System. Henrik T. Cedergren, Stockholm, Sweden. Filed Jan 28, 1902.

805,557. Electric-Current Generator. William Kaisling, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed May 31, 1904.

Miscellaneous.

805,439. Lightning-Arrester. Arthur J. Berry, Marion, O. Filed Feb. 25, 1905.

805,448. Magnetic Seperator for Ores. Henry F. Campbell, Melrose, Mass.; Jeanette L. Campbell, executrix of said Henry F. Campbell, deceased. Filed Jan. 20, 1904.

805,501-502. Method of Producing Chemicals in Electric Furnaces. Edward R. Taylor, Penn Yan, N. Y. Original application filed April 4, 1901. Renewed Feb 8, 1904.

805,619. Electric Signaling System. William S. Aungst and Arthur S. Aungst, Alliance, O., said Arthur S. Aungst assignors to said William S. Aungst. Filed March 20, 1905.

805,694. Method of Electrostatic Separation. Philip H. Wynne, Boston, Mass., assignor to Charles Henry Huff, Brockton, Mass. Filed Aug. 2, 1904.

805,735. Rear-End Contact Telegraph Key. Samuel S. Lefley, Florinel, Pa. Filed Aug. 26, 1903. Renewed July 13, 1905.

805.783. Electric Furnace. John S. Dorian, Niagara N. Y., assignor to Cora N. Dorian, same place. Filed March 27, 1905.

805,788. Electric Strain-Insulator. Samuel L. Foster, San Francisco Cal. Filed Jan. 16, 1905.

805,795. X-Ray Tube. John O. Heinze, Jr., Lowell, Mass. Filed March 16, 1905.

805,854. Magnetic Ore-Separator. Eric Hedburg, Joplin, Mo., assignor, by mesne assignments, to the American Reduction Company, Chicago, Ill. Filed Jan. 15, 4904.

806,018. Electromagnetic Relay or Sounder. Thomas M. St. John, New York City. Filed April 12, 1905.

806,039. Electric Heater for Oil-Wells. James E. Williamson and Charles E. Collins, Allegheny, Pa., assignors, by mesne assignments, of one-third to Amalia S. Connolly, Pittsburg, Pa. Filed Jan. 23, 1896.

806,052. Receiver for Wireless Telegraphy. Henry S. Blackmore, Mount Vernon, N. Y. Filed May 8, 1901.

THE TELEPHONE WORLD.

National Interstate Association Wants Maps.

Every Independent exchange manager in the United States is urged to send the National-Interstate Telephone Association of Cleveland, O., a map of the toll and long-distance lines owned or controlled by his company. In the work of compiling maps the association has been handicapped by not receiving the complete information necessary to show all the Independent lines in the different States. If all telephone managers will promptly comply with this request it will greatly simplify the making of these maps, which are of great value and benefit to every one interested in Independent work. It is to be hoped that every assistance will be given the association, and that maps of every State can be published showing the wide ramification of the Independent movement.

News from Birmingham, Ala., states that the People's Home Telephone Company will be able to re-establish its business much sooner than had been expected. Its switchboard. which was recently destroyed by fire, will soon be replaced by one of the Stromberg-Carlson manufacture, which will enable the company to put one-half of its telephones into service in a short time, and it will also give connection with the sub-stations in the suburbs of Birmingham at the same time.

Several telephone companies have recently been organized in Iowa, including the Caldwell Mutual Telephone Company of Exline, the Sheldon Telephone Company, capitalized at $15,000, the Terril and Lake Center Telephone Company of Terril, and the James Telephone Company, located at James, with Henry Junck president, and Frank Woolworth, secretary and treasurer.

The last link in the long distance lines of the American Telephone & Telegraph Company from Pittsburg, Pa., to Grafton, W. Va., a distance of about 109 miles, has been completed. The line follows county roads all through Fayette County, coming from Pittsburg by way of Perryopolis.

A special meeting of the stockholders of the Southern Bell Telephone & Telegraph Company has been called for December 13 to vote on a proposition to increase the capital stock of the company from $1,000,000 to $30,000,000.

The Pleasant Valley Telephone Company, a new organization, lately began work constructing a line south from Sauk Center, Minn. Its object is to connect the rich farming district in Pleasant Valley with Sauk Center.

A telephone line from McEwan, Tenn., through Humphreys County to points on Hurricane Creek is in course of erection. Dr. Robertson and P. J. Fuqua are the prime movers in the enterprise.

The Home Telephone Company of Mobile, Ala., has begun the work of putting down 300,000 feet of wires underground for use in the system.

Telephones Wanted by Long Island Farmers.

One of the peculiar results of the recent development of suburban and rural Long Island is the rapidly growing demand for telephones on the part of farmers. This is not confined to the more up-to-date farmers in the immediate outskirts of the metropolitan centers, but has extended to the more remote districts. A man who has just returned from a tour of inspection in Suffolk and Nassau Counties said recently:

"There has been a marked demand for telephones among farmers out on Long Island, and, while at first sight, this statement may seem strange, the reasons for the demand are perfectly rational, when attention is given to the great changes that have taken place on Long Island in the last four years.

"The demand is not specially for the various local telephone services, but for the regular metropolitan telephone connections, and especially for the long-distance lines. The demand is being forced upon the farmer by circumstances. It is the epicurean market dealer in Manhattan and Brooklyn that is forcing the long-distance telephone on the farmer. In his search for the most tempting edibles, the club and high-class chef encourages the specializing of vegetable raising among farmers, and the one who can raise a strange variety of vegetable, is sure of a steady demand for it, and payment of fancy prices from the city chef.

"This is where the long-distance telephone becomes imperative to the farmer who makes a specialty of raising new varieties and forms of vegetables, and this is the reason why so many regular service telephones are being installed in lonely, out-of-the-way farms out on Long Island."

The Washington & Monroe Telephone Company of Marietta, O., capitalized at $5,000, was lately incorporated by E. D. Amos, William Kette, Cyrus McHugh, W. J. Moore, C. A. Amos, B. C. Cline and J. O. Swallow. The incorporators will establish a line connecting New Matamoras, Woodford and other cities in those two counties.

The old ordinance granted the New State Telephone Company of Sault Ste. Marie, Mich., several years ago, and under which it is alleged the Michigan Telephone Company has been operating, has been repealed by the common council of that city. It is held that the Bell Company had invalidated whatever right it might have had under it by charging a higher rate for telephones than the franchise called for.

W. M. Denton, owner of the telephone franchise at Willacoochee, Ga., has begun the work of putting in the system. It is understood that the line will be extended to McDonald, connecting Pinebloom, Leliaton, Kirkland, Pearson and McDonald. With this work complete there will be telephone service in every section of Coffee County.

A lively telephone rate war is on at Rockwood, Tenn. The citizens are opposing a plan of the Cumberland Telephone Company to increase the rates for service.

Automatic Telephones.

At a meeting of the board of directors and the executive committee of the Consolidated Telephone Companies of Pennsylvania, of which the new telephone company of Wilkes-Barre is a part, held in their offices in Allentown, orders were placed for the installation in that city of an automatic telephone exchange of 4,000 lines, and similar exchanges of smaller capacity in Hazleton and Emanus.

The automatic system will embrace all the latest features in this, the highest development of telephony, since its inception.

The plant in Allentown will alone cost nearly $75,000, and will be installed in from three to four months. The Hazleton exchange will cost $25,000.

The new exchanges will be supplied by the Automatic Electric Company of Chicago, which has supplied exchanges of large capacity to many of the leading cities.

Harper, Kan., it is claimed, has more telephones installed in homes and business houses than any other city in comparison to its size in either Missouri or Kansas. There are 400 telephones in the place, which has a population of not more than 1,600. There are about 300 houses in the town, including places of business. There is an average of one telephone in each residence, and two telephones in each of more than one-half of the business houses.

The Central Home Telephone Company, capitalized at $5,000,000, was incorporated last week in Dover, Del. The incorporators are Edwin L. Barber, of Wauseon, O.; Joshua D. Powers, Louisville; John C. Monteleith, Bloomington, Ind., and James E. Bergen, Nanticoke, Pa. The company, it is said, will operate in Western Kentucky and Tennessee.

A deal has been closed whereby the Northwestern Telephone Exchange Company of Minneapolis, Minn., bought of Dr. F. W. Epley, the telephone exchange at New Richmond, Wis., its franchise, which runs until September, 1906, and its tributary rural lines. The transfer took place December 1.

A company has been formed at Mountain View, Ark., for the purpose of putting in a local telephone exchange. The officers are: J. L. Lancaster, president; Cebern Brooks, secretary; S. S. Brewer, treasurer.

A called meeting of the board of mayor and aldermen of Pulaski, Tenn., lately put a quietus on the telephone agitation there, by the withdrawal of all propositions from the Long Distance Company and the abandonment of its efforts.

The Billings & Red Rock Telephone Company of Billings, Okla., with a capital stock of $30,000, has been incorporated by Roy Henry, Rozelle Henry and Nannine J. Carter, all of Billings.

The Vicksburg & Yazoo City, Miss., Telephone Company reports to the Railroad Commission that its receipts for the last quarter were $195.80; operating expense, $132.65; net revenue, $63.15.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Atchison, Kan.—A contract has been let by the town board of Rushville for an electric light plant to furnish lights to the town, and also to furnish electricity for home consumption and manufacturing purposes. Work has begun on the plant.

Aurora, Ill.—The city council has under consideration the building of an electric lighting plant.

Beaumont, Tex.—R. C. Duff, A. Landry, John H. Brooks and others, are organizing a company to operate an ice factory and electric light plant.

Cheyenne, Wyo.—At a recent meeting of the city council, Mayor Collins decided to establish an electric plant in Basin, and a 25-year franchise for that purpose was granted.

Edwardsville, Ill.—This city and the McKinley Syndicate are arriving at a conclusion on the latter's petition for a franchise to operate an electric power and light plant in this city.

Elgin, Ore.—Messrs. Spencer and Sappington have purchased the electric light plant in this city from H. V. Gates & Co.

Forest, O.—The town council has awarded a contract for the lighting of this place by electricity.

Fremont, Neb.—The city council has decided to buy four 150 hp. horizontal boilers and a tubular 500 hp. heater for the municipal electric light and water station.

Glen Gardner, N.J.—At a regular meeting of the Lebanon Township Committee, the Lebanon Electric Light Heat & Power Company made an application for a franchise to erect poles and suspend wires for the purpose of lighting the streets and alleys of Lebanon Township. The president of the company is Charles V. O'Donnell, and Joseph C. Farr is the secretary.

Key West, Fla.—The Consumers' Ice & Cold Storage Company, of which F. H. Ladd is president, has applied for a franchise and will install an electric light plant.

Lawrence, Kan.—At a special meeting of the city council the contract for lighting the city was awarded to the Lawrence Electric Light Company, whose bid was $5 a month per lamp for 25 lights to burn all night, and $4 a month per light for 65 lamps to burn until 12:30. The lights are to be 2,000 cp., and the work of installing the system is now being done.

Litchfield, Ky.—The new city council gives assurance of an electric light plant and waterworks.

Muskegon, Mich.—The Muskegon Heights council has been considering the advisability of installing an electric lighting and water plant and will report favorably on the proposition at its next meeting.

Oakesdale, Wash.—The town council has granted an electric light franchise to the Moscow Light & Power Company of Moscow, Ida. The power company has the privilege of installing a plant here or bringing in power from outside.

Ozark, Ark.—Local parties contemplate installing an electric light plant and waterworks. R. M. Adams can give information.

Passaic, N. J.—This city is agitating the question of a municipal electric light plant.

Red Wing, Minn.—Capitalists from Detroit have secured control of the gas and electric light plants of this city, and will expend a large sum of money improving and developing them. The syndicate now owns 18 such plants. P. C. Thompson, F. A. Platt, Ralph L. Aldrich and A. E. F. White compose the syndicate, which will take possession January 1. The local management will remain the same as before.

Springdale, Ark.—Spencer Owen has secured a franchise to construct and operate an electric light plant.

Thomasville, Tenn.—The citizens at a special meeting voted to incur a debt of $30,000 for the purchase of a municipal electric light and power plant. The plant to be purchased is that of the Thomasville Electric Light Company.

Twin Valley, Minn.—Frank Magnuson has decided to install a new electric lighting plant here.

Watertown, Tenn.—A movement is being planned to give this town electric lights in the near future. No definite plans have been formed, but live interest is being shown and the city hopes to soon be enjoying the benefits of a complete light plant.

STREET RAILWAYS.

Avondale, Pa.—Tracks are being laid for a trolley road from here to West Grove.

Douglass, Tex.—Early in the coming spring electric cars will be run in this city.

Evanston, Ill.—Another electric line for this city that will tap the West Side and run north to Wilmette and south to the proposed Ravenswood extension of the Northwestern Elevated Railroad has taken form in a draft of an ordinance which was presented to the city council recently.

Five Lakes, Mich.—The electric line surveyors are now at work here.

Macon, Ga.—The Macon Railway & Light Company will expend $50,000 in enlarging its plant and power houses.

Marshall, Mo.—A proposition is now under consideration to build an electric railway between here and Sedalia.

Mt. Carmel, Pa.—The construction of a trolley line from this city to Locust Gap is now under way.

Muncy, Pa.—A charter has been granted by the State Department for the construction of an electric railroad from this city to the upper end of Hughesville, a distance of about six miles.

Paxton, Ill.—An electric railroad is expected to run through this city, starting at Danville, and running to Pontiac.

Roosevelt, Okla.—A charter has been granted the Wichita Mountain Traction Company of Hobart to build 50 miles of electric line from here to Apache, costing $250,000.

Syracuse, N. Y.—General Manager John J. Stanley, of the Rapid Transit Company, is anxious to have the proposed connection between the Solvay and West Genesee street electric lines as soon as possible.

Zanesville, O.—It is stated that the Ohio Power Company of this city has amended its charter so as to permit it to construct an interurban line connecting Newark. also to furnish light and power for the cities named.

POWER PLANTS.

City of Mexico, Mex.—Preliminary arrangements have been made for the installation in the mining district round about Parrel and Minas Nuevas, Mexico, of a mammoth power plant to utilize the waters of the surrounding mountains in creating electric power for a large number of mines. A large tract of land has been bought, and it is proposed to organize a Company with a capitalization of $10,000,000 to build and equip the plant. American capital will be given opportunity to secure control of this great enterprise.

Huntsville, Ala.—Representative Wm. Richardson, of the Eighth Alabama District, will introduce in the approaching session of Congress a bill granting a large Philadelphia electrical concern a franchise to develop the power of the Mussel Shoals in the Tennessee River. The engineers of the company have reported that there is enough power at the shoals to supply every city within a radius of 200 miles with the electricity it requires as well as to light every farm-house within that territory.

BIDS WANTED.

Abbeville, La.—Bids addressed to George W. Summers, secretary of Abbeville, will be received up to 3 P.M., Monday, December 18, for furnishing material and doing the work necessary for the construction of a waterworks and an electric light plant. Material and work includes the following: Brick buildings, pumping engines, boilers, steel tower and tank, cast iron pipe, hydrants and valves, automatic engines, direct current generators, electric wire and pole line material, machinery erection, pipe laying, drilling wells, sewer material and construction. Specifications for the above will be furnished upon application to W. Mackintosh, engineer, Abbeville, and plans can be seen at engineer's office, in this city. Bids for construction work must be accompanied by certified check for 10 per cent. of the amount of the bids. The right is reserved to reject any or all bids. J. R. Leguenec, mayor.

Cincinnati, O.—Bids will be received about January 15 for a power plant for the new Fourth Street Hotel. This part of the improvement will cost in the neighborhood of $100,000.

Washington, D. C.—Sealed proposals will be received at the office of the Building Committee, United States Department of Agriculture, this city, until January 5, 1906, and then opened for the installation of the electric wiring and conduit system of two laboratory buildings for the United States Department of Agriculture, in accordance with the drawings and specifications, copies of which may be obtained at the office of the Building Committee, United States Department of Agriculture. All applications must be accompanied by a certified check for $50, made payable to the disbursing clerk of the Department of Agriculture, which checks will be retained until the return of the drawing and specifications. B. T. Galloway, chairman.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 17⅞@18c.; Lake 17¾@18c.; casting, 17½@17¾c.

Brooklyn Rapid Transit was the weakest of the tractions on Monday, declining 2 per cent.

The Atlantic Telephone Company now offers to pay New York City $7,750,000 cash for a franchise.

It is reported that the Chicago Subway has secured a loan of $3,000,000 from Kuhn, Loeb & Co. to carry on construction work.

The West End Street Railway Company of Boston has declared the regular semi-annual dividend of 4 per cent. on its preferred stock, payable January 1.

At the annual meeting of the stockholders of the Metropolitan Street Railway Company of New York on Monday the retiring board of directors was re-elected.

The General Electric Company has declared the regular quarterly dividend of 2 per cent., payable January 15 to stockholders of record December 16.

Advices from Albany, N.Y., say that more than 99 per cent. of the total $5,000,000 outstanding stock of the United Traction Company have been deposited within the time limit.

The Chicago City Railway Company has declared the regular quarterly dividend of 2½ per cent., payable December 30. Books close December 12 and reopen December 18.

The Keystone Telephone Company of Philadelphia reports that from July 1 to October 31 its gross earnings were $264,804; net earnings, $123,668; fixed charges, $71,527; surplus, $28,325.

The transfer books of the American Telephone & Telegraph Company, for purposes of the special meeting to be held December 21, will be closed from December 14 to December 21, both days inclusive.

Directors of the United Railways & Electric Company of Baltimore have decided not to pay at the present time the December coupon on the cumulative income bonds, this being the fourth consecutive coupon in arrears.

The Auburn & Syracuse (N.Y.) Electric Railroad Company, having paid 4 per cent. on its preferred stock the last fiscal year, has increased its dividend rate to 5 per cent. It paid 1¼ per cent. on November 1 for the quarter ending September 30.

A report from Chicago says that National Carbon Company's net earnings this fiscal year (ending January 31) will be nearly $1,000,000, an increase of $150,000 over the preceding year, after usual depreciation, etc. This will be equivalent to 5¼ per cent. on the common stock, which will probably receive another dividend of 1½ per cent. early next year. During the company's seven years' existence it has written off $1,400,000 for depreciation.

Eastern interests in the Chicago Traction properties are looking for developments during the next few weeks. It is expected that the ordinance, which has been drawn up, will be passed by the common council of Chicago and vetoed by Mayor Dunne. The franchise case comes up in the United States Supreme Court on January 2. The controlling interests in the property feel reasonably sure of a decision in their favor. If they do win they will be in a much stronger position to dictate with respect to any subsequent ordinance that may be presented. If the company fails in the Supreme Court the controlling interests think that an ordinance, such as is now under consideration, should be regarded fair.

EDITORIAL NOTES.

Low Fares and Electric Traction.

Though not a new idea, the direct dependence of he public for relief from high fares rests upon the development of electric lines parallel to those demanding exorbitant rates. But the high charges of steam roads in certain localities is not necessarily an effort to gouge the public. It is essential that a rate be set which will net a profit, and this attempt is always the basis for criticism. But the point of importance is this: that if a local steam line is operating under such conditions that its transportation charges must be high in order to show profitable runs, then either the fare must be lowered in spite of claimed deficits or the road shut down entirely. It is inevitable in such a case for an electric road to parallel the steam line, and offer the public the same transportation at less cost. The meaning of this transaction is simply this—that to practical railroad managers transportation is like anything else which may be sold. The merchants competing for supremacy try conclusions with each other by variations in price. In the same manner rate wars have occasionally broken out all over the country between the different roads, perfectly similar to the steamship rate war recently ended among the transatlantic systems. When public sentiment is aroused over certain charges made for commodities or transportation, regarding them as excessive, the simple remedy of competition is always at hand as a weapon of defense.

In this respect electricity has served as the heavy fire gun. The steam roads' far-sighted managers see in the electric car and locomotive the future of all traction systems, whether short or long. They cannot fail to recognize the inevitable signs of transformation in railroad conditions—which will sweep away the entire steam equipment as surely as that equipment displaced the post chaise and its relays in the last century. Low fares will therefore be the result of this establishment of electric traction systems; first, between near-by points, and then between more distant centers, until the entire country is covered with a co-ordinated network,

The consideration of these facts may not make it dignified to carry conclusions further than the immediate necessities of the hour indicate, but at least the inexorable logic of events will be the means of shaping the future, in a broad and national sense, as it has been the means of transforming local conditions in a variety of isolated instances in a more constricted sense. In other words, it has been clearly shown by the rapid settlement of suburban territory, that the trolley car has exercised an almost magic influence in creating around the core of the older settlement a band of contiguous, well-established and prosperous homes and industries. The further the trolley extends, just as much further the streets extend. The most powerful means therefore, potentially and actually, of extending the populated centers of a given community, are electric traction. What is true of a well expanded center of population is also true of other units of the same character. And what is a nation but a series of cities and towns? If between them all the great highways of traffic, commerce and transportation, are energized by electricity, a species of regeneration will transpire. Sluggishly developing towns will take on new life, and the influx and reflux of people under the influence of lower rates for transportation will establish civic stability and enterprise, where only flimsy coherence before existed.

Electric traction and lower transportation rates will stamp this epoch as unique by emphasizing such typical features in our national history.

* * *

Rotaries in Power Schemes.

Power schemes have been readily furthered by the advantages derived from the application of rotaries to convert alternating into direct current and the reverse. But the developments in this direction have not been limited to the mere expansion of power propositions either in the abstract or the concrete. They have been of the highest value in drawing attention to the fact that their introduction has meant a new elasticity in the application of electricity in specific directions. This elasticity may be more aptly defined as an ease in sending considerable quantities of power in various directions over given distances for use in particular cases, with an average uniformity of efficiency that clearly betokens the highest standard of transmission.

The beneficial consequences arising from this method have been found in the spread of tunnels, electric lights and street railways. The tunnels projected could not succeed if the air were fouled to any extent, as it would by the use of steam locomotives. Electricity in this case, as in that of the others, when obtained from a series of sub-stations, readily solves the problem of widening the circle of electrical effectiveness. It may be said, without reservation, that the abundant success of electrical enterprises is pivoted upon the present established success of rotary coverters and power house equipments. Whatever the use of large or small quantities of power may mean, it at least means that any increase in the consumption, is a certification of an addition to the quantity of power, and, therefore, of the rotaries converting it for transmission and distribution.

Diversity of Lighting in New York.

The specialist in lighting must feel fully satisfied in viewing New York that whatever is marked down in the category of lighting possibilities is employed in the effort to produce illumination in the store windows of our main thoroughfares.

The diversity of the lighting systems in vogue is perhaps to be included as one of the striking features of this great cosmopolis. There is extant, particularly in the business streets, a "light hunger," if it may be so called. Gas, Welsbach, Nernst, arc, incandescent, vacuum tube and mercury vapor lamps are in constant use throughout the city. The streets are now lit by Welsbachs, with brilliant arcs at consecutive corners. Broadway is a curious scene, a medley of lights. Predominating over all is the arc, incandescent and Nernst, particularly the former two. At isolated intervals the brilliant greenish glare of the mercury vapor, or the dawn-like glow of the vacuum tube, creates a contrast on the greater background of yellowish glitter. From a technical standpoint these phrases of illuminatian are significant, not only as actual steps in practical lighting, but as a means of judging of the degree to which each system has been perfected. Economy as thus exemplified is to be best regarded as a belief that the best light is the cheapest. Not, however, the apparatus costing too much to install, or even the cheapest bright light, which the greenish glare of the mercury vapor amply discloses, but the most suitable to store and window illumination on the one hand, and street and corner lighting on the other. It is a good thing that the attitude preserved toward innovations is one of respectful attention, and not of discreditable criticism. This is particularly true at present, for the reason, as already stated, that the demand for bright and cheaply installed light, is always on the increase, not the decrease. In all probability, the city of New York is not only the most brightly lit city in the world, but the city lit by the greatest variety of systems of lighting as well.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A new development in electric welding is the automatic production of continuous rolls of wire fencing, says the "Iron Age." A number of galvanized wires are fed from reels arranged vertically and parallel to each other, and from another reel placed transversely to these are cut off lengths of wire, which are fed horizontally across the vertical wires. Where the horizontal and vertical wires intersect, these are welded together by means of small transformers. The welded section then moves forward a predetermined distance, and the operation is repeated.

◆

It is not unlikely, says the "Electrical Engineer," London, that, with Russia's attention being first directed to affairs in the Far East and then towards the pacification of her internal disorders, many of her industries must be adversely affected by reason of neglect and unsettled conditions, and of these, the fate of the platinum industry in Russia is viewed with most concern by electricians.

◆

Advices from abroad state that the Swiss Government has decided to open the Simplon tunnel at once with electric traction. The length of the line through the tunnel is approximately 12½ miles, which makes it the longest tunnel line in the world. Five electric locomotives will at first be used.

◆

There is considerable talk these days regarding the adoption of the metric system instead of the system of weights and measures now generally in use in this country. Unless the metric system is adopted throughout every line of business, it will lead to much confusion and unnecessary figuring.

◆

The Cunard liner Carmania, which in place of reciprocating engines, is equipped with the most powerful installation of model turbines yet conceived, has just arrived in this port. A description of the electrical features of this ocean greyhound will shortly appear in the columns of ELECTRICITY.

◆

The Bell Company's new stock issue of $150,000,000, which was mentioned in last week's ELECTRICITY, is explained in this way: "The company has sufficient cash in its treasury to meet its probable requirements until well into the year 1906, but it is desired that the requisite authority to issue bonds should be conferred upon the directors that they may be in a position to take advantage of any favorable opportunity that may arise, and to act promptly upon any financial plan that may seem advantageous."

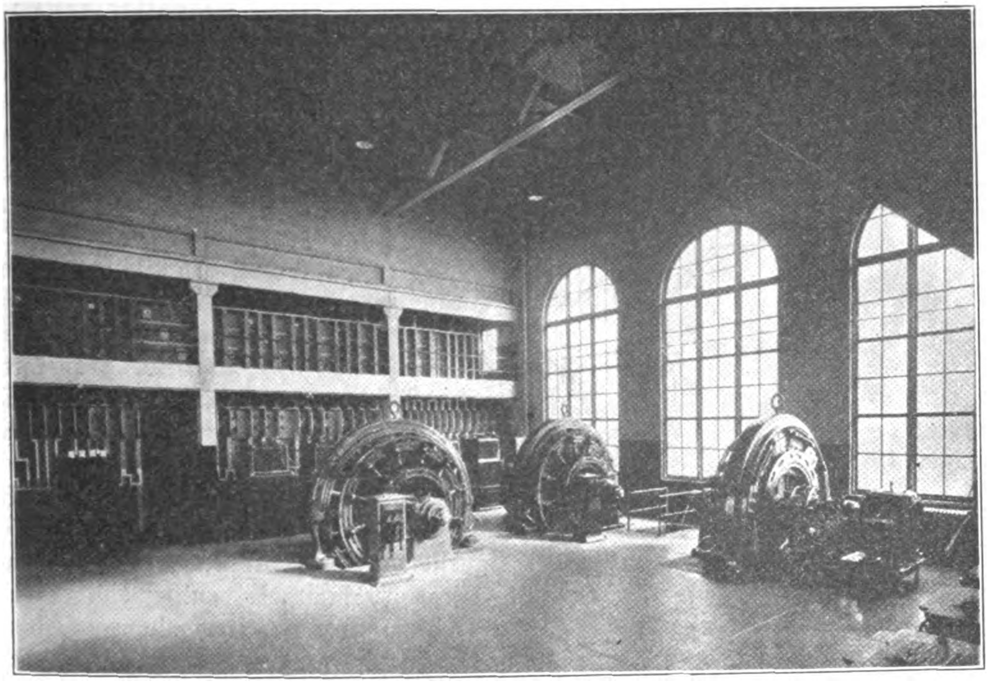
◆

Probably many are aware that the River Rhone in Switzerland on leaving the canton of Geneva, near Bellegarde, disappears in a subterranean gulf, and does not re-appear on the surface of the earth for some considerable distance. This geological phenomenon will soon be a thing of the past, as three proposals are now being studied for the construction of a barrage and of a canal for the reception of the waters of the river. The projects in question comprise the construction of a barrage of 25 meters in length, two parallel tunnels of 4,600 meters, two generating stations, and a waterfall of 58 meters with a total power of 155,000 hp., capable of being supplied for three hundred days in the year. The total cost is estimated at $5,000.000.

THE ELECTRIFICATION OF THE LONG ISLAND RAILROAD.

BY A. FREDERICK COLLINS.

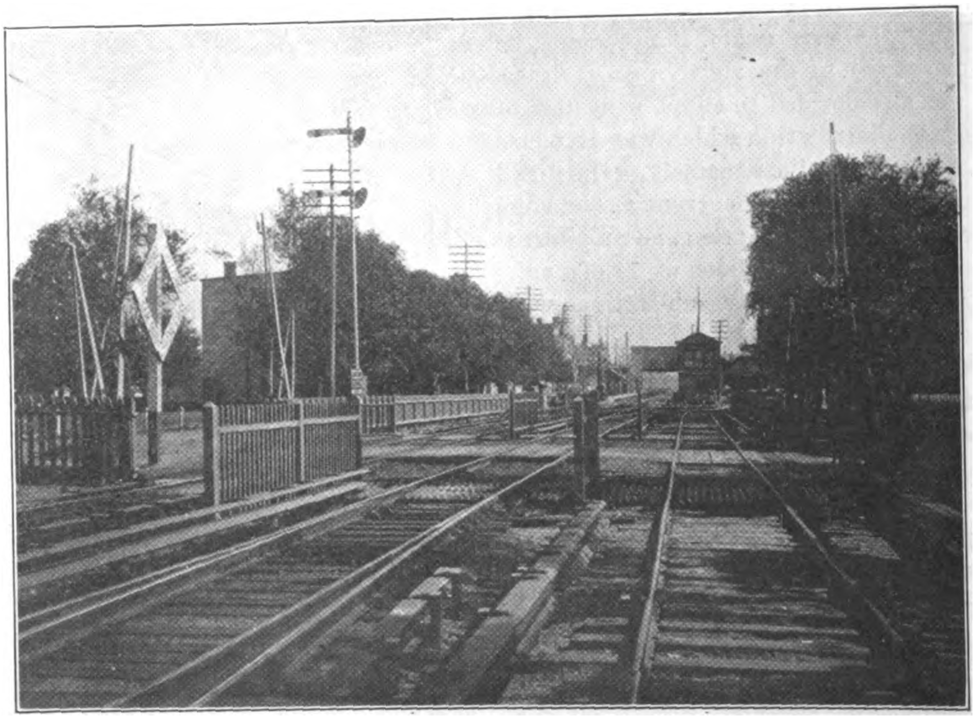
The Western Division of the Long Island Railroad consists of numerous lines within the limits of the City of New York, and while the main terminus of the road is in Long Island City, opposite 34th street in Manhattan, the road has another very important terminus at the intersection of Atlantic and Flatbush avenues, Brooklyn. The line from Jamaica to East New York originally traversed an open farming country, but the enormous growth of the outlying districts of Brooklyn resulted in building up almost solidly this section and beyond to a distance of a little over five miles.



Interior View of East New York Sub-station, Showing High Tension Switching Galleries.

In an agreement with the City of New York the railway company undertook to remove its tracks from the surface of Atlantic avenue, and to operate its passenger trains by a motive force not requiring combustion locomotives. This requirement obviously pointed to the utilization of electricity and to devise a satisfactory train service in this short section has resulted in the most extensive system of electrification yet put into operation on any steam railway in the world.

The Flatbush Terminal, as it is known, is in the heart of the Borough of Brooklyn and connects at that point with the Brooklyn Rapid Transit elevated lines leading to the Brooklyn Bridge and to the Broadway Ferry, and it will also connect with the subway tunnels now in process of construction by the Interborough Rapid Transit Company from the Battery, Manhattan, under the East River, and thence at Flatbush and Atlantic avenues. It will be seen that upon the completion of the subway tunnel passengers arriving at the Flatbush Avenue Terminal from various points on Long Island will have a short and direct route to the lower business section of Manhattan Island by either the subway or by elevated over the Brooklyn Bridge. Besides these facilities, direct connection will be established by the elevated lines over the new Williamsburg Bridge. The regular service at the Atlantic avenue station consists of not only suburban trains carrying passengers from the south and north shores of the island, but also a heavy local business from Flatbush avenue out to Jamaica and a very heavy excursion business to Rockaway Beach, and three different race tracks, located at Aqueduct, Metropolitan and Belmont Parks respectively. The nature of this varied traffic complicates the train service to such an extent that it was obviously impossible to adopt an electrification plan which contemplated electric haulage over a portion of the route and steam haulage over the remaining part, inasmuch as the traffic of passengers to the principal points would result in endless confusion and delay.

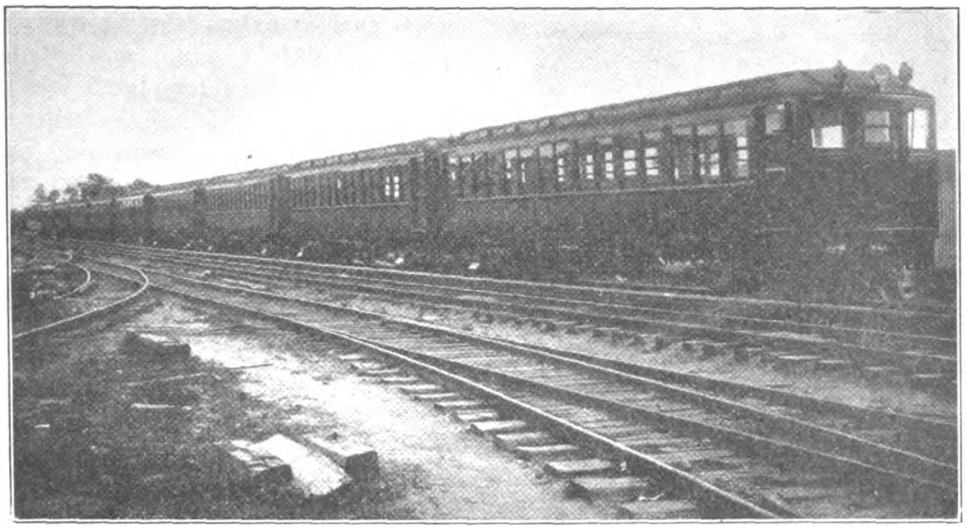


Third Rail Layout at Highway Crossing Near Woodhaven Junction.

Consequently it was decided, in spite of the fact that immediate returns on the heavy financial outlay could not be expected, to electrify all the suburban and excursion lines leading out of the Flatbush Avenue Terminal. This practically resulted in the electrification of the entire road south of Atlantic avenue and the main line out to Queens, and as far east on the Montauk Division as Valley Stream. It was not deemed necessary to electrify the line north of this, as no through traffic from Flatbush avenue to the terminal in Long Island City at present exists.

The diverse character of the train service and its very fluctuating loads at different seasons of the year, due to the excursion business, formed an extremely unfavorable condition for economical electric traction, for the reason that the load factor on any of the fixed portions of the complete system, as the power house and transmission lines, would of necessity be a low one throughout the year, except at certain seasons during the summer months.

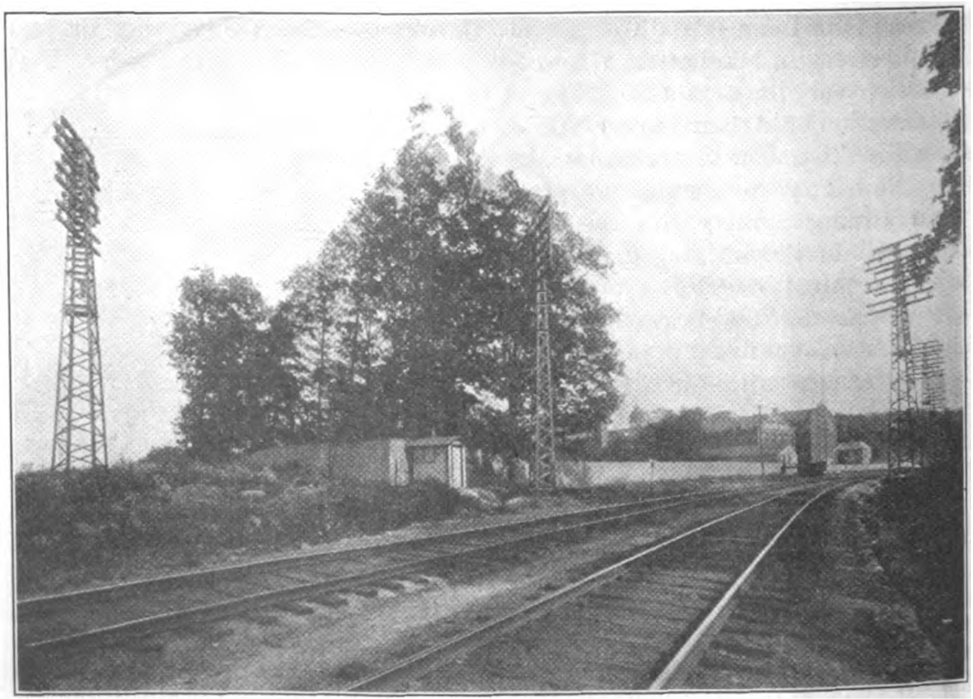
Notwithstanding these untoward conditions, which meant an enormously heavy initial expenditure, the management of the road determined to provide a complete electric service at the outset, having faith that the improved facilities afforded would result in the growth of the territory adjacent to their line and in the end afford them a fair return on their investment. In deciding upon a system the possibilities of connecting with the lines of neighboring companies had to be considered, and the operation of the rolling equipment over elevated lines, in subways, on the surface and also in the tunnels, had to be unified and harmonized so that the cars could, if necessary, be run over any of the above named lines. It was also decided to adopt a system of electric distribution which was standard on the adjacent lines, namely, a third-rail contact and a direct current at 600 volts for the propulsion current and an alternating current transmission at 11,000 volts for conversion at the sub-stations were provided.



View of Train of Steet Cars.

This high voltage current will be generated at the large power house, now nearly completed at Long Island City. This power house will be eventually one of the largest in the world, and has the distinction of being entirely equipped with steam turbines. At the present time three Westinghouse-Parsons turbines of 5,500 kilowatts capacity are installed, and the engine room provides facilities for three similar units. The three-phase currents thus generated are carried in conduits through the built up portion of Long Island City as far as the railroad yards. From this point the cables are brought overhead and carried on a specially designed lattice steel pole mounted on concrete foundations.

The sub-stations have been located at junction points wherever possible, such points being more practicable, for it is at these places the heavy loads occur. The locations also make it possible and convenient for the arrangement of transfer switches for the high-tension circuit. There are five sub-stations, the one at Woodhaven Junction being the largest; it is now provided with an equipment comprising three 1,500 kilowatt rotary converters and nine static transformers of 550 kilowatt capacity. Ultimately this station will be doubled in capacity. The Grand avenue sub-station has an equipment of three 1,000 kilowatt rotary converters and nine static transformers of 375 kilowatt capacity.



Steel Poles at Crossing.

All of these sub-stations, it may be stated, have foundations of sufficient size to accommodate much larger machines, the idea being that as soon as the present sub-stations reach their maximum capacity the electrically equipped railway will have extended far enough to warrant the building of more sub-stations at greater distances on Long Island. The 1,000 kilowatt converters will then be moved from their present stations to those further out, and in their places converters of 1,500 kilowatt capacity will be installed. The Rockaway Junction sub-station is provided at present with two 1,000 kilowatt rotary converters, and six static transformers of 375 kilowatt capacity.

The East New York sub-station has an equipment of three 1,000 kilowatt rotary converters, and nine 375 kilowatt transformers, and the sub-station at Hammels has two 1,000 kilowatt rotary converters and six 375 kilowatt transformers. This sub-station has also, in addition, a storage battery of 2,000 kilowatt hours capacity, making it the largest storage battery in the world in use for electric railway work. Its installation was deemed expedient, owing to the fact that the Hammels sub-station is the furthest from the power house and the unusual exposure of the transmission line, which is carried over Jamaica Bay for four miles. Again, the load at Hammels is very light during the winter, and the very large battery capacity makes it practicable to shut down the rotary equipment for much of the time during the winter months.

The appearance externally of the sub-stations is very much alike, all being built of brick and steel and fireproof construction throughout. They also conform closely in their interior arrangements, the rotaries and transformers being set up on the main floor, while the main switchboard is placed in a gallery on one side of the building from which the operators have an uninterrupted view of all the machinery under their control. A novel feature in connection with the sub-station is that all of them are provided with means for augmenting their capacity to the extent of 1,000 kilowatts, should such an emergency arise, through the use of portable sub-stations. These consist of steel cars, each carrying 1,000 kilowatt rotary converters and three static transformers. Two of these portable sub-stations have already been built and are in use. While the use of portable sub-stations is not altogether new, yet it is interesting to know that they are being used on a larger scale in this installation than has ever before been attempted. One reason for their extensive use is found in the fact that no feeders are used for supplying the third rail, the high conductivity of these permitting feeders to be dispensed with for all ordinary conditions of traffic. The direct current at a pressure of 600 volts is led directly to the third rail from the different sub-stations and is carried in this way to considerable distances. Great care has been taken in the installation of the third rail so that the safety of pedestrians may be assured, and much ingenuity and money has been spent to attain this result.

The third rail is laid 27 inches from the gauge line of the tracks, the standard distance adopted by the various roads, and it is covered throughout its length by a wooden sheathing held in place by brackets attached to the rail. Wherever the rail is led in part at stations a special side sheathing is attached to both sides, making it practically impossible for pedestrians to come in contact with it. At either side of a grade crossing the third rail terminates in a broad sloping shoe, and this is considerably within the line of protecting fences which inclose the entire right of way.

The trains at present are made up entirely of steel motor cars, of which nearly 200 have been equipped, but eventually the trains will comprise both motor and trail cars in the ratio of three to two; that is, a five car train will consist of three motor cars and two trail cars, the motor cars being 1, 3 and 5 respectively. All the cars will be furnished with the Westinghouse pneumatic multiple unit system of control and each motor car has two motors of 200 hp. each, both of which are carried on the same trucks that is, each motor car has a motor truck at one end carrying two motors, one geared to each axle, while the truck at the other end of the car is a "trailer," and carries no motor.

These cars are quite similar in design to the steel cars used in the Manhattan subway, and are constructed throughout of steel and finished in aluminum. Each motor car weighs 83,000 pounds, and is capable of maintaining a speed of 55 miles per hour. A noticeable feature in their operation is that there are no jars nor jerks experienced when they are attaining their maximum speed under short headway, and the trains are brought to a stop in the same even manner.

When it was decided three years ago to electrify the Long Island Railroad, Westinghouse, Church, Kerr & Co., were engaged to act as engineers and constructors, the entire work being under the direction of Mr. George Gibbs, who is chief engineer of electric traction, while the general features of the work were under the supervision of the electrical committee of the road, composed of various officials. The construction work was under the supervision of Mr. George B. Caldwell, who acted as superintendent of that department.

Work was begun on the power house September 15, 1903, and the first turbine was run on January 6, 1905; the sub-stations were begun May 4, 1904, and completed July 7, 1905; the transmission system was started November 30, 1904, and finished May 27, 1905, while work on the third rail and bonding the tracks was begun October 6, 1904, and finished August 31, 1905, the whole system then being articulated and put into operation July 26, 1905.

LIGHT, HEAT AND POWER PRINCIPLES.—XII.

BY NEWTON HARRISON, E. E.

Eddy Current Losses.—In all cases where sheet iron is alternately magnetized and demagnetized the effect of the lines of force is to create within the iron an EMF. which causes minute currents to flow in it. These currents are sufficiently minute to be of little consequence individually, but collectively they are of such importance that unless checked a considerable percentage of the available energy will be uselessly dissipated. The method employed, namely, that of subdividing the iron, is successful if means are taken to insulate the sheets from each other. The thinner the iron sheets the less the waste of energy through the generation of eddy currents, and the thicker the sheets the greater the waste of power. Practice, however, shows that limitations of thickness are best found in a certain average, such as is commonly discovered in ordinary Swedish sheet-iron or its near equivalent of American manufature. The formula f eddy current losses takes into consideration the thickness of the iron, the volume of the iron, the cycles per second and the degree of magnetization, as shown in the following symbolic arrangement of these quantities:

$$W = 1.645 \times V \times f^2 \times t^2 \times B^2 \times 10^{-11},$$

where W = the watts wasted, 1.645 = a constant whose value is variable, though approximately as stated, V = the volume of iron in cubic centimeters, f^2 = the square of the cycles of magnetization per second to which the iron is exposed, t^2 = the thickness of the laminations in centimeters squared of the iron composing the transformer core, and B = the lines of force per square centimeter in the core. As may be noted by an examination of the formula, the watts wasted in the iron are directly proportional to the volume, indicating that the greater the weight of the core the greater will be the watts wasted through eddy currents. An increase in the frequency affects the iron somewhat differently however; doubling this means four times the effect developed before, tripling it nine times the original effect, etc., as noted by f^2.

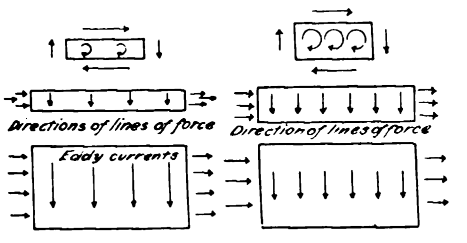
Eddy current Loss 100 watts
Eddy current Loss 1000 watts

Effect of doubling and tripling the thickness of core plates of a transformer.

Varying the Thickness of the Iron.—

Increasing the thickness of the iron is evidently the means by which eddy currents are rapidly multiplied. The reason for this is the reduction of resistance and the increased EMF. developed in the iron through its greater effectiveness as an inductor. For instance, if an iron plate .1 of an inch thick generates EMF. in a given field of magnetism, and the thickness is increased to .2, then not only in this case is the EMF. doubled, but the resistance of the plate is halved, thus raising the current to four times its original value. In other words, the most important practical elements in eddy current losses are the thickness, the lines of force and the frequency. The formula for EMF. which considers the relationship between the conductors, lines of force and speed in an armature is applicable here in showing the nature of the increase in waste energy in the iron plates through either an increase in the lines of force per square centimeter, the frequency per second of the current or the greater or less thickness of the iron plates. To take a specific case, suppose it is desirable to know how many watts are being wasted in 1,000 cubic centimeters of iron, composed of plates of .1 of a centimeter thick, the iron exposed to a series of 100 cycles per second at a magnetization of 5,000 lines of force per square centimeter, then the following data appears: $t = .1$, therefore $t^2 = .01$; $f = 100$, therefore f^2 10,000; $B = 5,000$ therefore B^2 25,000,000, and $V = 1,000$ cubic centimeters. Applying these items to the formula give the following: Watts wasted in eddy currents: $W = 1.645 \times .01 \times 10,000 \times 25,000,000 \times 1,000 \times 10^{-11}$ is equal to $1.645 \times .01 \times 10^4 \times 25 \times 10^6 \times 10^3 \times 10^{11} = .41125 + 10^{13} \times 10^{-11} = 41.125$ watts.



Eddy currents developed through thickness of the iron.

More eddy currents through greater thickness of the iron.

EFFECT OF THICKNESS OF IRON ON EDDY CURRENTS.

The feature that plays an important part in calculations of waste power in the iron is that of the rise in temperature. This increase in heat is due to two ineradicable causes: First, the heat of transformer coils, both primary and secondary, and second, the hysteresis and eddy currents of the iron itself. The consequence of this heat is the increased resistance of the iron plates, and the reduced waste of energy due to the eddy currents. On the other hand, the rise in temperature of the iron is a cause for a reduction in permeability, which if permitted to reach too far will not only affect the insulation and magnetizability, but absolutely limit the capacity of the transformer. Cooling methods are therefore advisable for purposes which affect the entire operation as well as any one particular part. The calculation shows that for commercial thicknesses of wrought iron or mild steel, as is commonly used in transformer construction, the eddy currents are comparatively a negligible quantity. Where only 40 or more watts are consumed from this cause by eddy currents at the magnetization given, namely, 5,000 lines of force per square centimeter, this induction means a hysteretic waste of $1,658 + 1,000 + 100 \times 10^{-7}$ or 16.58 watts. But the value of 41 watts lost by eddy currents is based upon a thickness of .1 centimeter for the iron, as compared with the 16.58 watts lost through hysteresis. If the iron is reduced in thickness the eddy current loss will diminish greatly. For instance, if the iron is taken as equal to .05 cm. instead of .1 cm. then the calculation gives a value of $1.645 \times .0025 \times 10^4 \times 25 \times 10^6 \times 10^3 \times 10^{-11} = 10.28$ watts, or about one-quarter of the first value obtained.

coil
Alternator

Temperature of iron increased through eddy currents and hysteresis.

As a centimeter is about .4 of an inch, .05 centimeter is equal to .02 of an inch or $\frac{1}{50}$. The idea presented here is to show that the waste of power due to eddy currents will become very great unless the correct thickness of iron is adopted in its construction. In fact the figures show that doubling or tripling the thickness of the iron means four or nine times the waste of power. Also that reducing the thickness to one-half or one-quarter means reducing the eddy current loss to one-quarter or one-sixteenth of its former value.

Eddy currents loss with thin plates
Hysteresis Loss

Relative amounts of power wasted in thick and thin plates by eddy currents and hysteresis.

Rating of Transformers as to Temperature.—The American Institute of Electrical Engineers has passed certain rules and limitations regarding transformers, for the perpetuation of good service and a practical maximum working temperature in its parts as follows: "In transformers for continuous service, a rise of temperature of copper not exceeding 50 degs. C. (90 + 32 = 122 degs. Fahr.) as measured by change of electrical resistance of primary and secondary coils; and a rise of temperature of other parts not exceeding 40 degs. C. (72 + 32 = 104 degs. Fahr.) as measured by a thermometer laid against the part, the core, for example, under normal conditions as to ventilation. In the case of transformers intended for intermittent service, or not operating continuously at full load, but continuously in circuit, as in the ordinary case of lighting transformers, the temperature elevations above the surrounding air temperature shall not exceed 50 degs. C. (122 degs. Fahr.) as measured by resistance in electric circuits, and 40 degs. C. (104 degs. Fahr.) as measured by the thermometer in other parts after the period corresponding to the term of full load. In this instance, the test load should not be applied until the transformer has been in circuit for a sufficient time to attain the temperature elevation due to core loss. With transformers for commercial lighting, the duration of the full load test may be taken as three hours, unless otherwise specified." A further suggestion made by this eminent body, is that transformers should be overloaded 25 per cent. for a period of two hours, during which time the increase in temperature must not exceed 27 degs. Fahr. over the ordinary full load test, when they are to be rated for an overload of this value. If the lighting or power circuits cause a greater overload than this the temperature requirements must be strictly complied with, or the transformer will overheat, burn out, and thus become inoperative.

Effect on Hysteresis and Eddy Currents During Overload.—The effects of an overload on a transformer are discovered in the additional heating of the coils composing the primary and the secondary and possibly in the iron The heating of the iron increases, only because the hys teresis increases with any augmentation of the lines of force, or as indicated by the formula: Watts wasted = $nB^{1.6}$. The eddy current loss will also increase if the lines of force increase, because this is proportional to $f^2 B^2$ in the formula, these being the variable factors. An overload does not increase the frequency f, but if it increases the lines of force per square centimeter B, then $f^2 B^2$ is greater than before only because B^2 is greater. If the magnetizing forces of the primary and secondary coils equalize throughout the process of underload, normal load and overload, the iron core will not carry any more magnetism than a certain amount throughout these changes. As a result of such conditions, neither the hysteresis or eddy current loss will increase; but an increase of lines of force would readily increase both.

Effects of Increased Size in Transformers.—A relationship that must be understood in comparing the losses of transformers of different sizes, is one which affects their manufacture to a remarkable degree. It is that which explains the increase in heat with an increase in size as follows: A given transformer taken as a standard, which has a certain loss in watts through causes already enumerated, and a certain radiating surface, will in comparison with a transformer twice the size show that the larger one has eight times the volume of metal but only four times the radiating surface. In other words, the internal losses are eight times as great, while the power to radiate the heat is not more than four times that of the smaller size. The consequences of this state of affairs would obviously be a heavy rise in temperature, unless provision is made in one of two ways: First, to make the transformer very much larger, in fact so large that the radiating surface per watt wasted remains constant. Second, to supply some means of dissipating the heat rapidly enough from the transformer to keep it at a safely low temperature. Various methods are employed in central stations and large power plants among which may be noted the following: 1st, transformers designed in such a manner, that their natural radiating surface is greatly increased by means of extensions and ribs, an expensive method of proceeding; 2d, transformers cooled by placing the transformer in an oil bath, the oil being in communication with an outer shell to which its heat is communicated rapidly; 3d, transformers supplied with an air blast connected to blowers, which use up energy in keeping the transformers down to the right temperature; 4th, transformers cooled by means of a water supply system, which, being pumped around means a loss of power in this direction; 5th, combination systems consisting of means representing more than one of the above items in the cooling process.

Transformer with brass pipe system for circulating water when entire device rests in an oil bath.

Self-Cooling Transformers.—By constructing a transformer of such a size that all its radiating surfaces are increased sufficiently to express the ratio of two or three square inches per watt, would mean that a transformer whose core loss is 100 watts, and whose coil loss is 1,000 watts, would need at least 2,000 square inches radiating surface for its coils, and at least 200 square inches for its iron surface. A self-cooling transformer is therefore best understood as one whose iron mass is about twice as great as it actually need be in order to keep the iron cool; and whose windings are relatively to this iron mass too small. The expense pertaining to a transformer built on these lines is too great to be justifiable. It is equivalent to a case where it is necessary to make a motor or dynamo twice as large as is actually required for the power in order to get sufficient cooling surface.

Advantages and Disadvantages of Oil.—The advantages of oil in transformer service are sufficiently great to make this application an idea of the highest value. In the first place, oil is an insulating fluid which preserves the integrity of the transformer without electrical risk. But it also adds an element of fire risk which is its one great objection unless absolute precautions are taken to eliminate it. A spark flashing across cannot cause the injury to insulation with oil in use that would otherwise occur, but the comparative rapidity with which oil absorbs heat presents great advantages in holding the temperature down. Its use means a slow rise of temperature, an intact insulation, but a fire risk that may be regarded as dangerous. The appearance of sparks or disruptive discharges beneath the surface of the oil mean very little in comparison with the same discharges above or near the surface. When the inflammable parts catch fire with air present they instantly serve as a huge wick and destroy the apparatus. Care in installation is a reasonably safe guarantee in such instances.

◆

TEMPERATURE AND THERMAL RADIATION.

Before the London Physical Society Mr. James Swinburne recently read a paper on "The Question of Temperature and Efficiency of Thermal Radiation." It has long been known that various surfaces have different emissivities, and it is generally held that at a given temperature some bodies radiate a larger percentage of their total radiation in the form of light. This view is largely based on some experiments by Evans and Bottomley. Evans' experiments really show that if two filaments A and B of the same area but of low and high emissivities respectively are run to give the same light, the filament A of lower emissivity will give a higher efficiency, and it will give a still higher efficiency if run so as to use the same power as B. This is a natural consequence of the different emissivities, and does not at all show that A gives a higher efficiency at the same temperature as B. Professor Bottomley's experiments are criticised on the ground that he used no photometer, and his reasoning attacked on the ground that he makes the same slip as Evans in confusing difference of emissivity with difference of efficiency at the same temperature. It is urged that a body A at the same temperature as B cannot give out radiation corresponding to a higher temperature of B; for if it could, and A and B were inclosed in a perfectly reflecting space, A would heat B to a higher temperature than A. It may be said that A can have a higher efficiency than B, not by giving out rays corresponding to B at a higher temperatere but by omitting to give some of the longer radiations that B gives. If this were true, a hot body might be surrounded by a thin case of A lined inside with a substance which only emitted and absorbed long waves. The case would then take in long and give out short waves, though colder than the source. High efficiency or selective emissivity are always sought in polished, grey, or white surfaces like flashed filaments, platinum and other metal wires and rare earths. If there were such a thing, it should be found not in white but in black bodies, as a body which is a specially good radiator of light when hot should be black when cold. Lummer's curves of the distribution of energy for a "black body" and polished platinum are compared, and show somewhat higher efficiency for platinum; but the comparison is difficult. The behavior of flashed lamps and incandescent gas-mantles is explained by the difference of emissivity, without any need for selective emissivities.

The secretary read a letter from Dr. J. T. Bottomley, in which he stated that the author's paper seemed to be to a large extent an attack on his work on radiation. He could not see that Mr. Swinburne had made a single experiment in support of his proposition that "In the case of pure temperature-radiation, the light efficiency is a function of the surface-temperature only." No amount of discussion such as the author asked for could do anything to prove or disprove this proposition. He failed to see that the author had worked out any logical proof of the proposition. The author had assumed that he (Dr. Bottomley) was incapable of matching the light-giving properties of two platinum strips placed side by side and properly arranged for this sort of comparison. The matching is exactly the same in principle as in shadow photometry, and in all the cases cited in the paper to which Mr. Swinburne takes exception, Dr. Bottomley's determinations agreed with those of his assistant, Mr. Evans.

Dr. J. A. Harker expressed his interest in the paper, and said that the question of radiation was of practical importance in the measurement of high temperatures by electrical resistance methods. He asked if two platinum thermometers, one bright and the other blackened, but identical in other respects, were transferred from an ice-bath into a sulphur-bath, would the final temperatures of the two thermometers be the same, and also would the thermometers approach their final temperatures at the same rate?

Prof. H. L. Callendar, referring to Dr. Harker's questions, stated that if the sulphur-bath was in an isothermal inclosure, the two wires would reach the same ultimate temperature although the blackened one would reach it quicker. The difference, however, would be small. With fine wires the loss of heat by conduction through the gas is more important than the radiation loss. The loss by radiation is proportional to the surface but the loss by conduction is not, and it therefore becomes relatively more and more important with the fineness of the wire. With regard to the action of incandescent mantles, he thought the author's theory was reasonable and satisfactory.

Mr. Maurice Solomon said he did not agree with Mr. Swinburne's contention that in the case of solids there was no such thing as selective emissivity, but that all bodies at the same temperature radiated light of the same efficiency. Selective emissivity existed in the case of incandescent vapors, and if it was consistent with the laws of thermodynamics in such a case, it could not be inconsistent in the case of an incandescent solid. With reference to the incandescent mantle, the explanation put forward by the author did not seem satisfactory. It was difficult to believe that the very small differences in color between a thoria, a thoria-ceria, and a ceria mantle could account for the enormous differences in their candle-powers.

Prof. W. E. Ayrton referred to experiments which he had carried out which tended to show that the temperature of a Bunsen flame was lowered by an incandescent mantle. He had also found that small pieces of mantle heated in a platinum boat to various temperatures just below the melting-point of platinum never looked brighter than the platinum. If, however, a small hole was made in the bottom of the boat and coal-gas passed in, the mantle immediately became brilliant.

Mr. Swinburne, replying to Dr. Bottomley, said that his main argument was that he had not made experiments. In the investigation of a question such as that considered in the paper, it was possible to prove much by means of experiment, but it was also possible to attack the problem by thermodynamic reasoning. He expressed his interest in the fact that Prof. Callendar had referred to his views as reasonable.

Telegraph Lines in Alaska.

A party of 30 men is constructing a military telegraph line between Rampart and Fort Gibbon, Alaska. The new construction is on high ground, will do away with a loop through the low, marshy, and dangerous ground of the Lower Tanana, and will obviate difficulties experienced in maintaining communication between the two points. A military telegraph line between Valdes and Fort Egbert, a distance of 422 miles, was interrupted during the past month for only five hours. This is considered a remarkable record, in view of the character of the country traversed. The United States cable ship Burnside is now at Tacoma, preparing to lay a short cable between Forts Lawton and Ward.

ELECTRIC MOTORS IN THE MACHINE SHOP.

BY W. H. WAKEMAN.

ARTICLE II.—(*Concluded.*)

Fig. 6 illustrates a radial drill with a tilting table, driven by a 5 horse power motor that seems to be an inseparable part of the machine because it fits so nicely into its place on top of the post. This motor is of the open type, as there is no good reason why this kind should not be used in an ordinary machine shop.

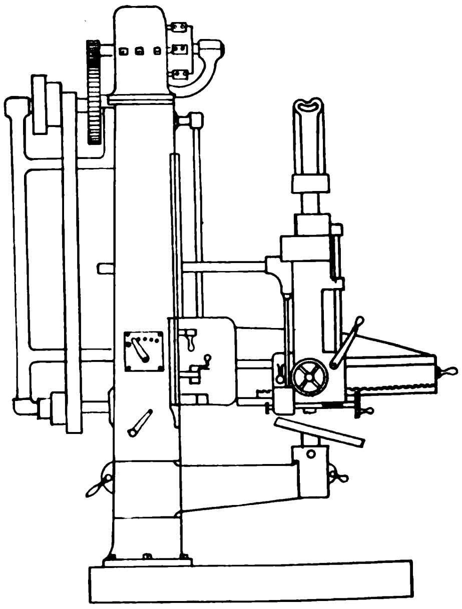

FIG. 6.

Drills of different sizes may be run at varying speeds according to size of drill and kind of material worked, therefore a variable speed motor gives satisfaction because its speed can be changed so easily.

Fig. 7 resembles Fig. 6, but it is of the portable type of radial drill, with a vertical motor at the top. The round post sets into place to hold it firmly upright, where it may be used on heavy work located in that vicinity. When this is finished a chain is attached to the arm near the post, a hook suspended from an electric crane is hooked into it, and the whole machine is carried away to another place where wires are attached and the motor set in motion in much less time than it would require to move one of the pieces to be drilled.

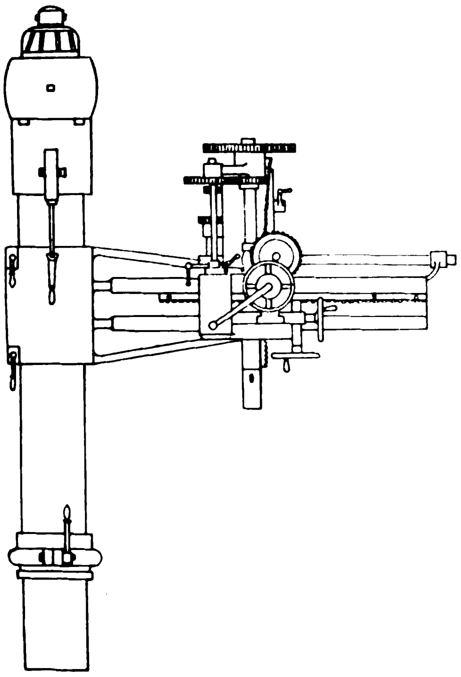

FIG. 7

Fig. 8 is a turret lathe driven by electric transmission of power. It has twelve speeds forward and the same number backward, enabling the operator to use it to the best possible advantage.

Fig. 9 is an extension base shaper, driven by a variable speed motor, which may be run from 300 to 1,600 revolutions per minute. This kind of a machine requires a very solid foundation that will not tremble when much stress is thrown upon it by rapid reversals of the table.

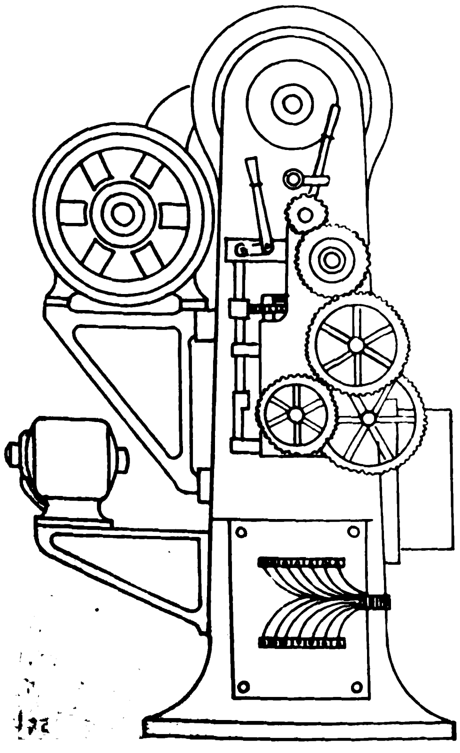

FIG. 8.

The independent motors admit of placing this machine near the side or end walls of the shop where the floor is more firm than near the middle of the room, whereas I have seen them placed in very unsuitable places because they must of necessity be placed near the line shaft to be belt driven. In some cases it has been necessary to build special piers under these machines in order to make it possible to use them and turn out good work.

Other illustrations from machine shop practice might be presented, but enough has been shown to demonstrate that with this kind of power transmission many advantages can be secured that are not a part of any other system, therefore it becomes necessary for all who wish to secure their share of work along this line to prepare for competition with those who are thoroughly up-to-date.

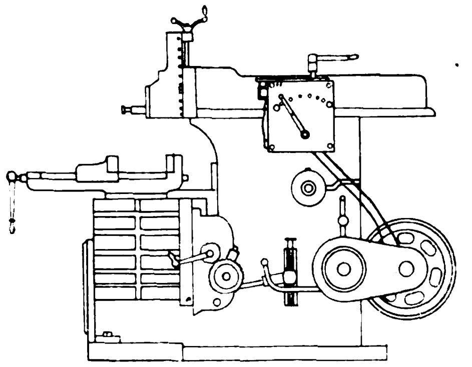

FIG. 9.

STREET CABLE SYSTEMS.*

BY S. J. WATSON.

In an electrical power plant the capital outlay on feeder, distributor, and service cables usually represents about two-fifths of the total expenditure.

The large investment involved, coupled to the fact that the satisfactory maintenance of the supply depends so much on the absence of faults and leakages makes it necessary that careful consideration should be given to the design and arrangement of such systems.

Serious breakdowns to the generating plant or accessories causing interruptions in the supply are fortunately rare, which speaks well for the attention given to this portion of the undertakings, but the technical papers almost weekly report a failure of the supply in one town or another through defective mains.

The old saying "Out of sight, out of mind," has doubtless something to do with the development of faults to the breaking down point, as the cables lie buried below the surface of the street and cannot receive the same inspection as the other plant. All cable systems may be divided, broadly, into two classes: 1, Draw-in systems; 2, Solid systems.

A third type, what might be termed a semi-solid draw-in system as represented by the Brookes system, which consists of a closed metallic pipe or conduit into which insulated cables are drawn and the whole filled up with a heavy grade oil, has been used to a small extent. The principle is in many ways a good one, but it necessitates a continuous supply of oil under pressure, and this proves difficult and costly to maintain on account of leakage.

It is also difficult to classify under either of the above headings the various systems of bare copper in iron, stoneware, brick, or concrete conduits. The conductors are invariably copper tape from an inch to an inch and a half wide and an eighth to a quarter of an inch thick, resting on porcelain insulators fitted to the conduit every 3 or 4 feet. Heavy sections are made up of several tapes laid together. When the strip is laid on edge it must be considered a solid system, as the strip is wedged to the supporting and to the jockey insulators to prevent side sag, but if laid flat and strained up into junction boxes it may be claimed as a draw-in system. To insure the satisfactory drawing in of additional strip, the conduit must be laid reasonably straight and be provided with inspection boxes at frequent intervals.

A large amount of town lighting work has been carried out in the past with bare copper, and fairly satisfactory results are still being obtained with pressures up to 460 volts.

For heavy sections it is undoubtedly cheap, but owing to the increase in pressures from 110 to 220 volts and the consequent decrease in the sections required, and also on account of the large reductions in the cost of insulated cables, this advantage is not now of so much importance as it was 10 years ago.

The troubles experienced with bare copper have been caused principally through the leakage of water into the conduits from burst water-pipes or flooded sewers. Such occurrences not only lead to heavy leakages and the decomposition of considerable quantities of objectionable liquids, but it necessitates the subsequent opening up of the length to clean insulators, copper and conduit.

In many instances disastrous results in the way of blown-off street boxes have occurred, due to accumulations of coal or other explosive gases being ignited by the sparking across defective insulators. Trouble has also resulted from the wave action set up in the conductors when heavy intermittent currents or short circuits have had to be handled.

---

*Abstract of paper read before the Institution of Electrical Engineers Manchester, Eng., November 28, 1905.

DRAW-IN SYSTEMS.

Under this heading must be placed all systems with the cables drawn into pipes or conduits manufactured of wrought or cast-iron, stoneware, concrete, bitumen, fiber or other materials with one or multiple ways.

A single cast-iron pipe was probably the first to be used for the purpose. It offers several advantages, such as mechanical strength, long life, and is easy and convenient to lay with either spigot and socket, lead or rubber ring joints.

Wrought-iron pipes have been used, but in some soils it has but a short life, and may require frequent renewal.

For concentric or multicore cables either of the above-mentioned single way pipes may be used, but with a number of single cables, it is better practice either to use a separate pipe for each cable, which increases the cost or alternatively a multiple way conduit.

Multiple way cast-iron conduits can be obtained, but the cost is prohibitive except for quite special work owing to the difficulty in casting each way perfectly smooth and true.

Bitumen conduits with multiple ways have been used to some extent, the joint between lengths being made with molten bitumen compound after inserting an expanding mandrill into the ways to secure alignment. This material was not sufficiently strong and rigid to maintain its shape and with a slight increase in temperature through an overloaded cable or other cause was liable to collapse and form practically a solid system.

Probably the most largely used conduit with two or more ways are those made of stoneware. The cost is reasonable, the mechanical strength is sufficient for most positions without further protection, and its insulating properties are good. The material is, however, somewhat brittle and liable to damage when the ground is afterwards disturbed for other purposes, and as the lengths are from 2 to 3 feet it is difficult to support if a cutting of any considerable width is required under it. The joints between lengths of stoneware are made in several different ways. One maker adopts an expansive mandrill for centering, and uses a molten composition of bitumen and sand or ordinary cement outside a lapping of cloth, in both cases a cradle being used under the joint. Another maker uses a dowel for centering and cement for the joint. The type most generally used at present is provided with what is practically a bored and turned joint with the bedding faces of both spigot and socket made up of a pitch or bitumen compound. To make a watertight joint between lengths when laying the faces must be painted with a mixture of resin and tallow or of Stockholm tar and lightly hammered the lengths together. This method effects a considerable saving in time compared with other molten bitumen or cement, which delays the work while the materials set.

Multiple way concrete conduits have been extensively used for multicore air space telephone cables, the joints being made with cement.

A continuous conduit constructed of concrete has recently been designed and has been adopted by several supply undertakings. The leading features of the system consist of light gauge iron piping which before being used for the formation of the conduit is coated with a compound possessing a low melting point and good lubricating qualities. The pipes are screwed together and laid in the trench with suitable wood spacing bearers and the concrete is filled in, under, around and over the pipes. After allowing sufficient time for the concrete to set a steam jet supplied from a small boiler through a flexible pipe, is applied to the interior of the pipes, which causes the compound to soften and permits of the withdrawal of the pipes length by length. Some of the compound is retained by the surface of the concrete and presents a smooth surface for the cable when drawing in.

Cement-lined light gauge wrought pipes have been used largely in America, and also in England where work has been carried out by American contractors. The pipes are usually laid in concrete. Where cables are to be bunched together in one pipe this system may be cheap, but as this is not desirable, and the cost of several pipes would compare unfavorably with multiple way conduits, no special advantages appear to be offered by this system.

One of the latest design of pipes for draw-in systems is made of a patent fibrous material which possesses high insulating properties. It can be obtained of a light gauge with spigot and socket joints for laying in concrete or of a heavier gauge with screwed joints for laying direct in the ground without further protection. The material appears a very suitable one for the purpose, and its working under every-day conditions will be watched with interest.

A draw-in system of any kind is usually more difficult to construct than a solid system. Changes of level have to be arranged for to allow of the drainage of water from the ways. Boxes for drawing in or out must be provided at the corners of all the principal streets, at all changes of level and at intervals of 60 to 80 yards.

A small, but important matter with all draw-in systems is the provision of suitable ends to the ways at all street boxes. For this purpose hardwood bell mouthpieces turned or shaped to fit the ways can be used at little expense, the wood being first treated with Stockholm tar as a preservative. Faults on the cables of a draw-in system frequently occur at the street boxes through damage to the insulation, and attention to a small detail such as this will tend to reduce maintenance charges.

SOLID SYSTEMS.

The least expensive of all solid systems is armored cable, which consists of single, concentric or multicore insulated cables, with or without a lead covering and protected overall with steel tapes or galvanized iron or steel wires with a compounded serving outside, the complete cable being laid direct in the ground with a wood board over it as a protection. Such a cable can be quickly laid, and its flexibility is very useful in avoiding the usual obstructions met with under ground. In natural soil, such as gravel, sand or clay, satisfactory results may be obtained, but it is quite unsuitable without additional protection for laying in the made-up ground usually found in the main streets of our towns, as the armoring will be quickly destroyed and leave the insulation unprotected.

One of the largest used solid systems is made up of a wooden trough with wooden bridge pieces for supporting the cables, the whole being filled with molten bitumen. All the woodwork must be thoroughly impregnated with Stockholm tar. The usual preservative compounds used by building contractors for woodwork is not suitable for this purpose, as it has a deleterious action on the bitumen and some kinds of insulation. For the protection of the trough against future excavators a wooden trough, stoneware, tile, or old bricks may be used. Wood makes a very suitable covering carefully nailed to the sides of the trough. Tiles or bricks are apt to be displaced subsequently and leave the bitumen exposed.

(*To be concluded.*)

Proposals Invited.

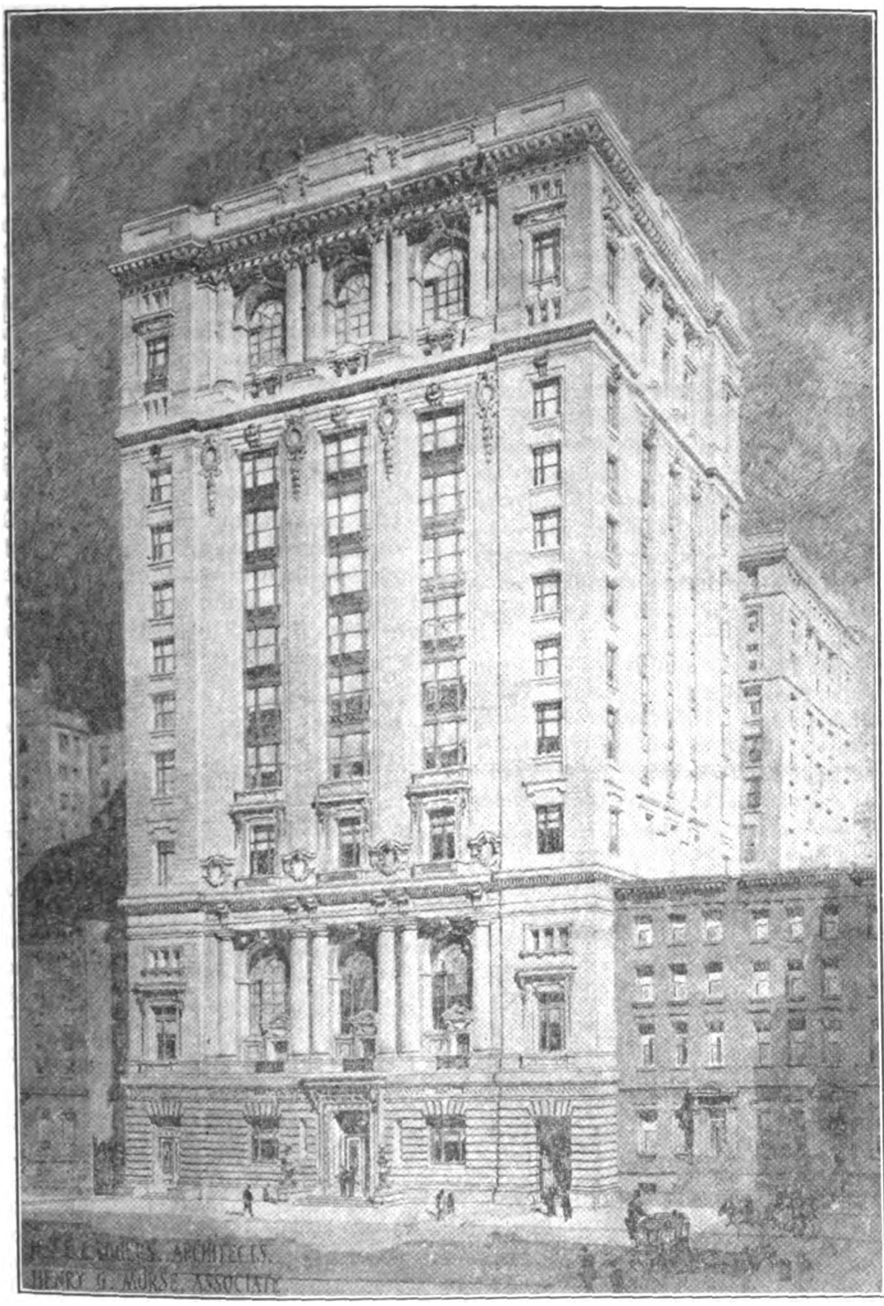
The Navy Department through the Bureau of Supplies and Accounts is inviting sealed proposals until December 26 for furnishing Eastern Navy Yards with the following supplies: Schedule 269, motor generator sets, conduit and fittings, wire, and miscellaneous electrical supplies; schedule 270, electric heaters; schedule 272, electric soldering irons. Specifications and proposal blanks can be obtained at the navy pay office in New York or upon application to the Bureau at Washington.

On January 9, 1906, the Bureau will open bids for furnishing Western Navy Yards with the following: Schedule 276, motors, cable, circuit breakers, electrical supplies. Proposal blanks and further information can be obtained upon application to the Bureau.

The Bureau will also open bids on January 9 for furnishing Eastern Navy Yards with machine tools as follows: Schedule 281, electric hoist and runway; schedule 282, electric driven motor outfit, arbor press, milling machine, etc. Blank proposals can be obtained at the navy pay office in New York, or by applying to the Bureau.

The War Department, through the constructing quartermaster at Vancouver Barracks, Wash., is inviting sealed proposals until December 30, for furnishing electric light fixtures, wattmeters and transformers for three buildings at that post. Full information will be furnished intending bidders on application to the constructing quartermaster at the above named post.

THE ENGINEERING BUILDING.



Perspective of the Engineering Building, looking northwest, to be erected on 39th street, between Fifth and Sixth avenues, New York City. It covers five city lots, and is presented by Mr. Andrew Carnegie for the American Institute of Electrical Engineers, American Society of Mechanical Engineers, American Institute of Mining Engineers and the Engineers' Club.

Non-Resident Lectures at the University of Minnesota.

Mr. J. M. S. Waring, of Chicago, gave a lecture before the Senior Electrical Engineers at the University of Minnesota upon "Storage Battery Engineering," on December 5, 1905. Mr. Waring outlined the principal uses of the storage battery, discussed the methods of operation, booster, and the advantages of the battery as a central station auxiliary.

As a concrete example of storage battery engineering, Mr. Waring discussed the reasons for the adoption of storage batteries by the Elevated Railway Companies in Chicago, and followed out in some detail the method of determining the location and method of handling the same.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DEC. 5, 1905.

Electric Lights and Appliances.

806,409. Portable Electric Lamp. John H. Goehst, Chicago, Ill., assignor to the Federal Electric Company. Filed Feb. 16, 1905.

806,516. Electric-Light Hanger. Hugh R. Berry, Greenville, Miss. Filed July 20, 1905.

806,723. Incandescent Electric Lamp. James C. Wormley, New York City. Filed Jan. 13, 1901.

Telephones and Telephone Apparatus.

806,276. Trick Telephone Toy. Edward G. Myers, Lincoln, Ill. Filed Jan 31, 1905.

806,284. Mouthpiece Attachment for Telephones. Metta F. H. Phillips and William B. Hubbard, Boston, Mass. Filed March 6, 1905.

806,339. Telephone-Shelf. Joseph S. Gold, Jackson, O. Filed May 20, 1904.

806,372. Telephone Attachment. Joseph Silverman, San Francisco, Cal. Filed May 26, 1905.

Miscellaneous.

806,173. Electric Furnace. Romaine W. Myers, Fruitvale, Cal. Filed Feb. 14, 1905.

806,238. Signal Apparatus. Clarence W. Coleman, Westfield, N. J., assignor to the Hall Signal Company. Filed July 1, 1905.

806,319. Automatic Signal. Andrew B. Burt and Frank T. Vanatta, San Francisco, Cal. Filed June 5, 1905.

806,332. Electric Clock System. Martin Fischer, Zurich, Switzerland, assignor to the Actiengesellschaft "Magnet," same place. Filed July 5, 1900.

806,363. Magnetic Tachometer. Edwin H. Porter and Burleigh Currier, Philadelphia, Pa. Filed June 17, 1905.

806,412. Telegraph-Repeater. Francis W. Jones, New York City. Filed Sept 21, 1905.

806,560. Electrical Measuring Instrument. Edwin F. Northrup, Philadelphia, Pa., assignor to the Leeds & Northrup Company, same place. Filed May 12, 1905.

806,574-575-576. Process of Making Insulated Wires, Insulated Wire and Process of Insulating Electric Conductors. George H. Rupley, Schenectady, N. Y., assignor to the General Electric Company. Original application filed Dec. 16. 1902. Divided, and this application filed Jan. 15, 1904 and March 1. 1905.

806,588. Electrical Insulator. Herbert Sinclair, Trenton, N. J. Filed May 5. 1905.

806,690. Electrical Ring-Furnace. Karl Meiser, Nuremberg. Germany. Filed April 26, 1904.

THE TELEPHONE WORLD.

To List Keystone Telephone Voting Certificates.

The voting trustees of the Keystone Telephone Company have filed application with the Philadelphia Stock Exchange for the listing of the $2,750,000 voting trust certificates. These represent an equal amount of common stock deposited with the trustees. The listing of the certificates will more than double the amount of Keystone common stock now available for trading, which aggregates 100,000 shares of the par value of $50, of which 58,000 shares are deposited with the voting trustees.

News from Milbank, S. D., states that at a recent meeting of the directors of the Grant County Telephone Company it was decided to extend the line from its present southern terminal, Stockholm, in South Shore, Codington County, and from there northwest to Summit. This will mean 35 miles of new line. Construction work will begin as soon as the weather permits.

Application was lately received by the board of governors of the Columbus, O., stock exchange for the listing of the securities of the Newark Telephone Company, the Independent company, which operates in Newark, O. The company will issue $50,000 of preferred stock which the brokers of Columbus will place for it. The preferred is paying 6 per cent. dividends, while 8 per cent. is paid on the common stock.

The Mountain Telephone Company, to operate in southern Berks County, Pa., has been organized by farmers and merchants. Work on constructing the line will be begun at once.

The East Lindley, N. Y., Telephone Company lately held a meeting to elect officers for the coming year. Sidney Griswold was elected president; William Griswold, vice-president; Bert Herrick, secretary; Abraham Brockhart, treasurer, and Fred Groom, director.

The Peninsula Telephone Company of Detroit, Mich., has made an agreement with the Oakland Telephone Company of Pontiac, to construct copper circuits, to be run through the Pontiac office and at Holly.

In Pierre, S. D., the total telephone tax for this year is $13,630.34, which is a decided gain over the tax paid a year ago, when $8,634.15 was what was required of the companies.

The Georgia Telephone Company has announced that its subscription list has recently increased to the number of 3,275 subscribers in Savannah.

The telephone question is being agitated again with very good prospects of securing a line through Leonard Bridge connecting with Lebanon, Conn.

The Idaho Independent Telephone Company of Boise has advertised for bids for the construction of a telephone exchange building.

The Interstate Telephone Company has begun the work of making extensive improvements to its system in Dolgeville, N. Y.

Growth of Farmers' Telephone Company.

The board of directors of the Baiting Hollow & Roanoke Telephone Company of Riverhead, N. Y., has voted to ask the stockholders to authorize the increase of its capital stock from $20,000 to $50,000, and it is believed that this will be done in the near future.

This company, started by farmers a few years ago to connect their farms throughout the rural districts, is having a phenomenal growth. It began with $5,000 capital. Only two or three years ago this was increased to $20,000, and now a large further increase is wanted.

In the beginning the farmers, in addition to operating the company themselves, built its own lines and installed its own 'phones. But lately the business has been increasing so rapidly that Joseph C. Backus, an expert, was put in charge as superintendent. The company had not been going long before it was found necessary to get into Riverhead with its lines. From that place the lines have rapidly spread in all directions, until now every village within a radius of a dozen miles is connected with its large central station, Riverhead. The farmers first put in the line as one of the up-to-date farming schemes and they believe it has been a money-maker for them on farming questions alone; beside this the company has annually paid big dividends to the stockholders. The increased capital will be used to extend the company's business.

Messrs. W. R. Fanning and H. R. Talmage recently met at Port Jefferson to make the final arrangements for an interchange of service with the North Shore & Suffolk Telephone Companies. Soon the local company will have a service all the way to Patchogue and various other south side and north shore villages.

The Springfield Home Telephone Company was recently incorporated under the laws of Tennessee with a capital stock of $75,000. The following officers were chosen: Thomas Pitt, president; John McMurry, vice-president; A. L. Dorsey, secretary, and H. T. Stratton, Jr., treasurer. Offices are being fitted up, and the construction of the system will begin at once. Much interest is being manifested in the enterprise by the public, and the venture has every evidence of being successful.

The Jacksonville Telephone Company, of Jacksonville, Ark., has filed a certificate increasing its capital stock from $1,000 to $10,000. S. W. Murtishaw is president, and Minnie S. Stone secretary of the company.

At a meeting of the board of directors of the Maryland Telephone Company of Baltimore, to be held the last Thursday in this month, the president, H. W. Webb, will retire from that office. He will be succeeded by Vice-president David E. Evans, who was Mr. Webb's predecessor.

The recently incorporated Franklin Telephone & Telegraph Company has about completed the construction of a telephone line from Quakertown to Riegelsville, Pa., with Springtown as its center.

Telephone Service Extended.

The recent deal by which the Citizens' Telephone Company of Cambridge City, Ind., obtained control of the Hagerstown telephone plant, is one of importance to that section. The two exchanges are being reconstructed, and when united free service will be extended to the patrons of both companies. The consolidation increases the number of 'phones to almost 1,600. The lines cover a strip of territory from Losantville, on the north, to within four miles of Connersville on the south, a distance of nearly 30 miles, and has direct connection with the entire Independent telephone system of the State.

The Citizens' Telephone Company of Terre Haute, Ind., an Independent concern, has purchased a block for its new exchange at a cost of $4,500. The property has a frontage of 45 feet and is excellently situated. Plans are being prepared for the erection of a new brick building three stories high, which will be as near fireproof as modern construction can provide. This will insure the absolute safety of the operating mechanism from fire risk. An elaborate switchboard will soon be installed, which will embrace all the features of up-to-date design, and it is estimated that the expense of erecting and fitting the building will reach as high a figure as $100,000. When this has been completed the Independent company will be in a position to furnish the highest class of service to the citizens of Terre Haute and vicinity.

The Columbus, O., Citizens' Telephone Company has recently installed an immense long distance switchboard, which is said to be the largest switchboard for long distance business installed in any Independent plant in the country. It will have 32 operators' positions, and will start in with 60 long distance lines, 32 Franklin County exchange connections and 60 rural and suburban connections. The company is also installing automatic telephones at the rate of 15 a day, and would put in 100 a day if it could obtain the necessary facilities and men. It is said that the scarcity of these ever since the new automatic system has been installed, has been a serious handicap to the extension of the system, so great have been the demands for the company's service.

The Mount Oarroll Mutual Telephone Company of Mount Carroll, Ill., was lately incorporated with a capital stock of $5,000, to operate a telephone system. The incorporators are Otho Watson, W. K. Stakemiller and Dan. S Mackey.

The improvements in the telephone exchange at Marlin, Tex., during the past few months have been extensive. Cables have been strung on all changes made looking to an up-to-date system.

The Summerville Telephone Company has finished the work of rebuilding its lines in Williamsport, Pa., and the service is now in an excellent condition.

J. L. Sayre, of Richwood, O., is organizing a telephone exchange for Ostrander and the district between Marysville and Delaware.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Andrews, Ind.—Nichols & Thornton have been granted a franchise to establish an electric light and waterworks plant.

Arcadia, La.—The plant of the Arcadia Electric Light Company was lately destroyed by fire.

Brillion, Wis.—The Brillion Electric Light Company has been incorporated with a capital stock of $20,000, by C. W. Behnke, O. C. Behnke and others.

Buffalo, N. Y.—The Referendum League, according to one of its members, will at an early date have one of the aldermen introduce a resolution directing the commissioner of public works to obey the recent vote of the people relating to a municipal electric light and power plant.

Canton, S. D.—The Canton Milling Company will sell $20,000 bonds to Eastern parties to enable it to put in a new electric light plant and waterworks system.

El Reno, Okla.—The El Reno Gas & Electric Light Company has been incorporated with a capital stock of $150,000 by George J. Hickox, F. N. Howell and others.

Fort Ann, N. Y.—The Wall Knitting Company will install an electric light plant.

Fort Morgan, Col.—This place will soon hold a special election to vote on the question of issuing bonds for the purpose of building and operating a municipal electric light plant.

Gilroy, Cal.—The Tracy Engineering Company has the contract to construct an electric lighting plant here.

Hyattsville, Md.—A bill will be prepared for passage at the coming session of the Maryland Legislature authorizing this town to borrow sufficient funds with which to install an electric lighting plant in the town for street and commercial lighting.

Marseilles, Ill.—Messrs. V. J. Duncan and J. J. Joy, of Ottawa, contemplate establishing a gas and electric light plant here.

New York City.—It is currently reported that this city will buy a piece of land 300 feet square at Port Richmond, on which to establish an electric lighting plant for all the street and public buildings of Richmond Borough.

Peru, Ind.—Capitalists of this city have obtained a franchise for an electric light plant at Arcadia, and the same plant will be used in providing electric lights for the streets of Atlanta, three miles distant.

Princeton, W. Va.—William E. Fowler, president of the American National Bank of Graham, has made application to the council for a franchise to erect an electric light plant here. Mr. Fowler binds himself to have his machinery on the ground within one month and the plant in operation by the first of June.

Pittsburg, Pa.—This city has concluded to build its light plant. The council authorizes the appointment of a joint committee of seven to investigate and procure estimates of costs, etc.

Union, N. Y.—A proposition for an electric light plant is under consideration here,

Zionsville, Ind.—The Zionsville Water & Electric Light Company of this city has been incorporated with a capital stock of $10,000, to erect, operate and maintain waterworks and electric light plants. The incorporators are: V. A. Longaker, D. S. Menasco and M. E. Wiesehan.

STREET RAILWAYS.

Centerville, Ia.—The Centerville Light & Traction Company is now making a survey between here and Mystic, with the object in view of determining the possibility and practicability of constructing an electric railroad between the two cities.

Ellisville, Ill.—One of the Walsh Brothers is trying to find out the best route for an electric railway in this town.

Fairmont, W. Va.—The directors of the Fairmont & Fairview Traction Company, which purposes to connect this city with Fairview by an electric railway, a distance of 20 miles, has elected the following officers: President, E. L. Rutherford, Scottsdale, Pa.; vice-president, S. L. Dillinger, Baltimore; secretary, Charles E. Conway, Fairmont; treasurer, B. F. Overholt, Scottsdale.

Fisher's Island, N. Y.—Steps have been taken to petition the Legislature for a charter giving privilege to operate an electric line here. The line contemplated would be a narrow gauge affair, and have very small equipment, so could be built at small expense. It is believed that the traffic for it would be ample to pay a dividend on the small outlay proposed.

Florence, Col.—F. F. Granger, who recently looked over the county with a view of building an electric line from this city to Coal Creek, Rockvale and Canon City, says that the country is too sparsely settled for a road to pay from the start. As the property along the proposed line would be greatly benefited by the road, he asks a cash bonus of $45,000 to help along the enterprise, said bonus to be paid only upon completion of the road,

Geneva, N. Y.—While promoters in this vicinity have been discussing the advisability of constructing a trolley road between Lyons and this city, a party of local capitalists went to Albany and incorporated the Geneva, Phelps & Newark Electric Railway Company, for the purpose of constructing and operating an electric railway between this city and the village of Newark. The company is capitalized at $40,000. The road will be about 15 miles long.

Granite Falls, Minn.—Business men of this city and Canby are talking of a trolley line between the two places.

Gridley, Cal.—A prominent citizen lately expressed the opinion that Mr. Butters' proposition to build the electric road into this city for free right of way and free terminal would be speedily accepted. Definite action will shortly be taken by the Chamber of Commerce.

Hummelston, Pa.—The people of this city are circulating the report that a number of capitalists are planning for a trolley line between here and Middletown.

Mt. Holly, N. J.—It is reported that a Philadelphia banker has offered to finance the plan of extending the trolley line of the Burlington County Railway Company from this place to Pemberton by way of Smithville.

Mt. Sterling, Ky.—Younger Alexander, J. M. Bigstaff, John Collins and others have been granted the right of way to build and operate an electric line to this city from Paris and North Middletown.

Oxford, Pa.—A new trolley line is being built to this place and Kennett Square.

Philadelphia, Pa.—The first active steps toward building an electric line between Camden and Atlantic City have been taken by the West Jersey & Seashore in leasing part of its Newfield branch and the entire Somers Point branch to the Atlantic City & Shore for 40 years. An electric system will be established between Atlantic City, Pleasantville and Somers Point. It is the purpose of the West Jersey Company to electrify its Newfield branch between Pleasantville and Newfield, and to build an electric line between Camden and Newfield, paralleling the steam road which extends from Camden to Cape May.

Utica, Ind.—Ebenezer Howes, of this city, is at the head of a movement to build an electric line from this city to a connection with the Louisville & Southern Indiana Traction Company,

POWER PLANTS.

Cobourg, Ont.—The Northumberland-Durham Power Company, Limited, with a capital stock of $750,000, has received a charter to construct and operate works for the distribution of electricity. W. J. Crosson, J. A. Culverwell, C. Donnelly, W. McLean, S. Nesbitt, R. A. Mulholland, W. J. Maher, J. F. Clarke, E. T. Adams and Frank M. Field, are among the local and Port Hope gentlemen who are interested in this concern.

La Crosse, Wis.—Black River promises to become one of the leading water power streams in the Mississippi valley under disclosures recently made by the La Crosse Hydro-Electric Light & Power Company, when articles of incorporation were forwarded to Madison. The company is capitalized with $1,000,000.

Oceanside, Cal.—That H. E. Huntington intends to construct on Warner's ranch, about 20 miles from here, a large power plant, has been shown by the filing in the county recorder's office at San Diego, of a notice of appropriation on 50,000 inches of the waters of San Luis Rey River.

BIDS WANTED.

Los Angeles, Cal—The board of Education of this city will receive bids for the electrical indicating instruments for the new Polytechnic High School. All bids must be accompanied by a certificate check of 5 per cent. of amount of bid.

South McAlester, I. T.—Sealed proposals for wiring, heating, etc., for the Indian Consistory will be received until January 15, 1906, at the office of William Busby, chairman, this city.

Washington, D. C.—Proposals for a brick industrial building will be received until January 2, by the Department of the Interior, Office of Indian Affairs, this city, for furnishing and delivering the necessary materials and labor required to construct and complete a brick industrial building, also electric light and water sewerage plants.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 18⅝@18⅞c. Lake 18¼@18½c.; casting, 18@18½c.

The United Railways Investment Company of San Francisco preferred stock has been placed on a 5 per cent. dividend basis.

For the five months ended November 30, the Philadelphia Rapid Transit Company claims it is over $400,000 ahead of the corresponding period in 1904.

The General Electric Company has filed with the Secretary of State at Albany, N. Y., a certificate of increase of capital from $48,325,500 to $60,000,000.

The Pittsburg Railways Company has closed a deal for the purchase of the Washington & Canonsburg Electric Railroad for $475,000 cash and $600,000 in bonds.

The Interborough Rapid Transit Company has declared the usual quarterly dividend of 2 per cent. payable January 2. Books closed December 11, and reopen January 2.

The Chicago Telephone Company has declared a regular quarterly dividend of 2½ per cent., payable December 30. Books close December 26 and re-open January 2.

The Otis Elevator Company has declared the regular quarterly dividend of 1½ per cent. on its preferred stock, payable January 15 to holders of record December 30.

The Twin City Rapid Transit Company has declared the regular quarterly dividend of 1¾ per cent. on its preferred stock, payable January 2 to holders of record December 19.

The Strowger Automatic Telephone Exchange at Chicago has declared the regular semi-annual dividend of 50 cents a share, payable January 2. Books close December 23 and re-open January 4.

The Electric Company of America warrants have been placed in the unlisted department of the Philadelphia Stock Exchange. It has been ruled that commission on these warrants be 6¼ cents per share.

The Massachusetts Electric Companies has just issued its sixth annual report covering the year ended September 30, 1905. The report shows gross earnings, $6,734,127; expenses, $4,456,303; net earnings, $2,277,824; charges, $1,543,514; balance, $734,310; dividends, $372,448; surplus, $361,862.

The Vanderbilt-Andrews Traction Syndicate is said to have purchased the entire property of the Rochester Railway & Light Company, which will complete its control of all the traction lines, gas works and electric lighting plants of Rochester, N. Y. The transaction is said to involve $10,000,000.

Contracts have been let by Edwin and J. B. Hanna and other Cleveland capitalists for the construction of the Chicago, Lake Shore & South Bend Electric Railway, which will connect Chicago and Cleveland by trolley as well as Chicago and Cincinnati. The line is expected to be completed by the end of 1907.

The statement of the New York associated banks last Saturday, while showing a deficit of $1,246,525 in surplus reserves was not what could be called a disappointment. At the same time, it makes evident the strained position of money in the clearing house center of the country. Some relief is afforded by the announcement that Secretary Shaw has authorized the payment of interest on United States bonds due January 1 and December 15. Account of interest anticipated is about $4,200,000.

EDITORIAL NOTES.

The Electrification of Steamships.

Not very long ago, the "Great Eastern," then called the "floating city," was supposed to represent the climax of steamship development as far as size and equipment were concerned. It was a side paddle steamer of great dimensions, with what was then considered every facility for passengers' comfort, and the making of rapid progress across the water. It may be remembered, that the first Atlantic cable was uncoiled from its hold and laid across the ocean, due to the spirit of enterprise animating the breasts of Cyrus Field and his colleagues.

The first great transatlantic steamer was therefore identified from the start with the greatest electrical project under consideration—the welding together of the American and European Continents. The "City of Bremen," another steamer crossing the Atlantic, became unique as the first ship to be equipped with an electric light plant. The success of the large steamship, of its accessories in the way of mechanical and electrical additions, soon paved the way for a series of improvements, that eventually became established factors in its general equipment. To-day this equipment is so varied in character that it may be said to mark two general lines of progress: one in the way of mechanical improvements; the other in the way of electrical advancements. The latter are in certain respects more startling in their purpose and application than the former. They represent inventions not only in the way of light and power, but remarkable forms of mechanism for signaling and receiving messages. The idea presented here may be said to embrace what can be consistently called the electrification of steamships. By this is not only meant the use of electricity to the purposes of personal comfort, but its use for the improvement of transatlantic service to an extent hitherto undreamed by the most imaginative of novelists. In this last respect, as a matter of verification, may be mentioned the printing of a newspaper, containing all the important items of American and European life. The development of a distinct press service at an inaccessible point on the ocean surface, means the concomitants of such a service. It means an ability to reach and communicate with either shore. It naturally adds an element of safety to ocean travel hitherto absent. It therefore improves the service to an extent which removes many of the terrors once associated with the phrase relating to "those that go down to the sea in ships."

The searchlight for signaling at night to nearby vessels has been a boon to the navigator. The wireless telegraphic device for reaching the farthest and darkest recesses of the ocean's surface has prevented isolation from civilization. The electric lighting, heating and hoisting apparatus has transformed the interior of the latest type of marine architecture into floating hotels. These things, with which we have become so very familiar, have been inaugurated by the possibilities of electricity. Fire risks in consequence are all concentered. Of all the awful possibilities of ocean travel, this, the risk of fire, has been reduced to a minimum by the replacement of oil lamps by the incandescent. Thus the electrification of steamships does not mean the singing of a note of praise, because they have been dominated by applications of electrical energy. But it does mean a new realization of benefits to life and limb, to health and happiness, of the many advantages in the way of hygienic surroundings that it permanently secures. It has been the means of encouraging ocean trips because, to use a popular phrase, "all the comforts of home" are by its means developed to their utmost. An ocean steamer of modern type is thus a great floating hotel, as much in certain respects a part of the soil, as though it were firmly imbedded at any of the noted resorts of amusement or health.

* * *

Adopting the Metric System in the United States.

To adopt the metric system in the United States it will be necessary to educate the public not only to its use, but its value, as well. No opposition will be met on this score by those familiar with the units it represents. Members of the House Committee on Coinage Weights and Measures, are anxious to commemorate their work by an advocacy of this system for general adoption throughout the United States. Already a matter that has been legalized by Congress, Representative Littauer of New York is about to call for legislative enactment making the use of the metric system a law. We, as exponents of electrical engineering, regard this possibility with great satisfaction, but the confusion into which artisans and shop dealers will be thrown is what strikes our attention. It will be a tremendous task to accustom the illiterate to the meaning of such names and values. It will be a still greater task to have that meaning penetrate the precincts of domestic life to an extent which will render orders from there intelligible to the dealers providing them. A generation must live and die before the metric system will be firmly founded in the United States. Between this time and that people will be bound to think in the English system, though they may talk the metric. Until this is done, however, confusion must result between our German and French and American exporters.

* * *

Undeveloped Electric Lighting in France.

France is a country in which progress comes in waves; at one time the dominant power is science, at another time politics—then follow tidal waves of art, music and literature. The neglect of electric lighting in France is either due to a disregard of the value of the electric light or to a lack of enterprise in furthering its general utilization. A reference of this kind is only made because France not very long ago possessed the full leadership in the electrical science, both as regards theory and practice. The brilliancy of her workers made her noted in all countries; the names of Ampere, Arago, Deprez, Plante, Faure, are immortalized in the archives of scientific progress. But her recent work in electric lighting is left in the background, in comparison with the vast strides made by America, England and Germany. The facilities for making electric lighting a success are not any less in France than in other countries. If the argument is advanced that the interior of France is settled by peasants, whose wants are few, then the same logic applies to Germany, where electric lighting is done to a large extent in rural communities. Electric lighting in France is not undeveloped in Paris or Havre or other large cities. But where every small town in our own land as well as England and Germany are well equipped in this respect, France is behindhand.

Provincialism may be the ruling factor there to a greater extent than it is in either of the other countries, but if so, a system of propaganda is necessary to instill new ideas into the minds of the agricultural class. Electric lighting in any country is largely a matter of education, as far as its spread is concerned. Until active means are taken in this direction the interior of France will lack, in this respect, what the other countries enumerated are so well noted for.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Work is progressing actively on the proposition to merge the leading street car manufacturing concerns of the country.

IMPROVED ARC FURNACE FOR MAKING SYNTHETIC DIAMONDS.

BY A. FREDERICK COLLINS.

The successful industrial applications of the electric furnace have opened a new field in chemistry, and the arc furnace, which is one of the three types available, has proven a means of obtaining temperatures so exceedingly high that it is not only possible to break down certain combinations, resolving them into simpler bodies, but also to build up other elements into new compounds.

In various preceding issues of ELECTRICITY, editorials and articles have appeared from time to time relating to the ingenious researches of M. Henri Moissan, of Paris, who was enabled by means of high temperatures and exceeding pressures to produce real diamonds, though these were of microscopic size. Since these famous essays of the French physicist other workers have striven to excel the product by improving the process, the latest claimant in the field being Mr. Henry W. Fisher, chief engineer of the Standard Underground Cable Company of New York.

The arc furnace in which the miniature gems are produced is formed by an electric arc in air between two carbon electrodes, similar to the arc light. When in operation there is a definite limit to the length of arc which can be maintained with a given current strength, and again the limit which at first increases very nearly in proportion to the current strength, does so slowly as the current density reaches higher values, and in virtue of this fact the length of the arc is limited. The temperature of the carbon terminals may reach a value approximating 3,500 degrees centigrade, which is practically the point at which carbon volatilizes when under atmospheric pressures. The incandescent gases of the arc reach a temperature of at least 1,000 degrees higher, and hence it follows that the arc furnace is particularly adapted for subjecting the small charges of iron and carbon necessary in making diamonds to the highest temperatures available.

Briefly, Moissan's method of crystallizing carbon is to place within the electric furnace a crucible of molded carbon, the electric arc being formed between the carbon terminals directly over the opening of the crucible. A small quantity of soft iron and pulverized graphite, the latter to be converted into the diamonds, were put into the crucible, the compound being finally covered with charcoal. A current of 1,000 amperes and 500 volts produced the arc between the carbon electrodes, which were 2 inches in diameter, and under the terrific heat evolved the graphite was brought to a temperature capable of fusing it.

When this result was attained the crucible with its incandescent contents was lifted from the furnace and immersed in water, the sudden cooling causing the iron to contract and in turn this action exerted a sudden and mighty pressure on the graphite. The fused graphite distributed throughout the molten metal was in consequence crystallized in the isometric system, having the density and other characteristics that distinguish diamonds from all other crystals. It has been found that the quicker the cooling process takes place after the maximum temperature has been reached the larger apparently and nearly perfect are the stones. It is evident, therefore, that in the experiments just cited a considerable loss of time results from the moment the furnace is opened until the liquid mass reaches the water or other cooling medium, and it was believed that if this could be reduced much better results would attend the work.

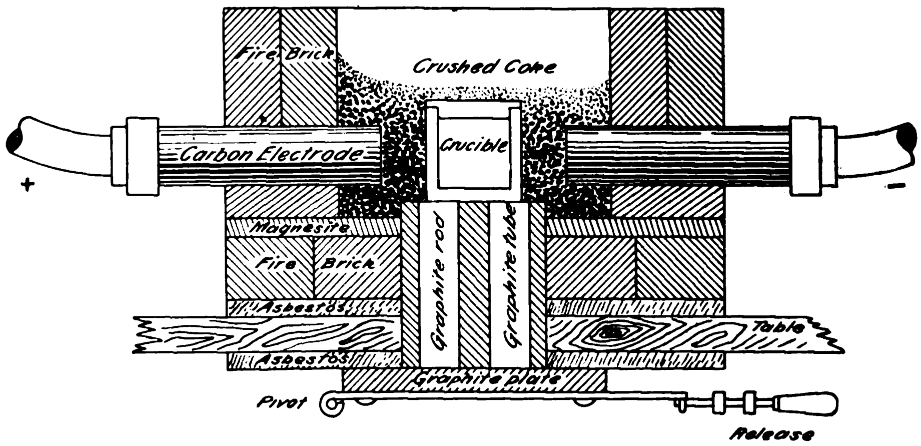

FIG. 1.

To provide means that would reduce the length of time required to transfer the crucible to the cooling medium, Mr. Fisher devised the furnace shown in Fig. 1, and which also enabled him to obtain a more intense and uniform heat. In the first place the table on which the furnace rested was well insulated from the heat with layers of asbestos, while the furnace itself was built up of fire-brick, and lined with magnetite; through the walls the graphite electrodes projected, the ends terminating on either side of the crucible and around which powdered coke was packed. In this manner much of the heat ordinarily lost where the arc takes place above the crucible is returned.

The lining of magnetite serves to distribute the heat set up in the interior of the furnace and thus the temperature of the exterior is considerably lowered. By referring to the cross-section, Fig. 1, it will be observed that a portion of the table immediately under the furnace has been cut away. The object of this is to permit the crucible and its contents to be dropped from the inside of the furnace when the critical period has been reached, and falling through a hollow cylinder of graphite only an instant is required to precipitate the seething mass into the cooling bath. The cross-sectional drawing also shows the simple device by which the crucible is released from its position inside the furnace; a hinged graphite plate having a releasing catch supports a rod of the same material, and on top of this rests the crucible; when the catch is drawn forward the graphite plate falls and the rod and crucible with it.

There is considerable danger attendant upon the immersion of an incandescent body in a fluid, and this very often results in violent explosions; this then was a feature that also had to be taken into consideration in devising ways and means for obtaining pressures. Several experiments with materials other than liquids were made and in some of the early ones a mass of lead having a large cavity drilled out of its center to contain the molten iron and the carbon suspended in it. This not proving over-successful a bath of the molten solder was tried, but this did not give much better results.

It was then the experimentalist returned to water as the best cooling agent and to utilize it to the best advantage he arranged a pivoted trap of asbestos to drop the crucible; disaster nearly attended these trials for the crucible in its fall turned partially over and projected its white-hot contents into the iron pot holding the water; striking the vessel at the water line there was a blinding flash, like miniature lightning, a terrific seething of decomposing water, and when the event was over it was found that the molten metal had burned a hole through the pot.

Fortunately, no one was injured nor any material damage done, but to prevent a recurrence of the untoward event, measures were at once taken to provide a course for the crucible that should in the future guide it in an upright position until it had come in contact with the water, and this eventually led to the graphite tube, as shown and described. When the superheated iron and graphite were treated to this sudden cooling process the now solidified mass broke up under the enormous strains, and it was in the portions that were broken off that the diamonds were found, while more were discovered in the larger portion that always remained in the crucible. The accompanying illustrations, Figs. 2 and 3, are micro-photographs of the gems, the first ever obtained artificially in the United States. The photographs shown were taken by reflected light, and indicate clearly the appearance of the product which is a colorless, transparent and crystalline form of diamond.

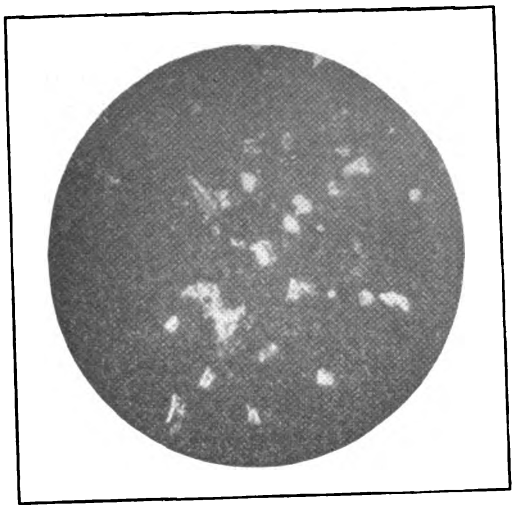

FIG. 2.

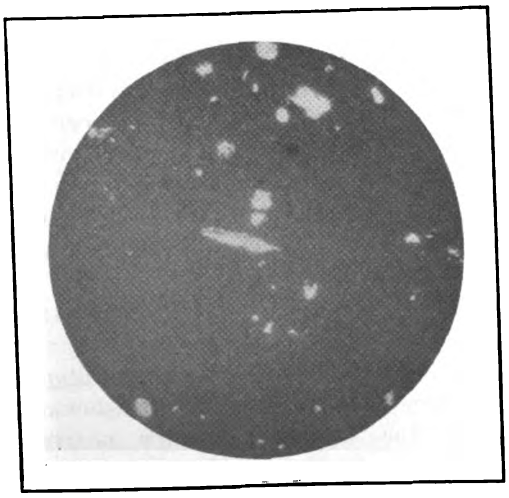

FIG. 3.

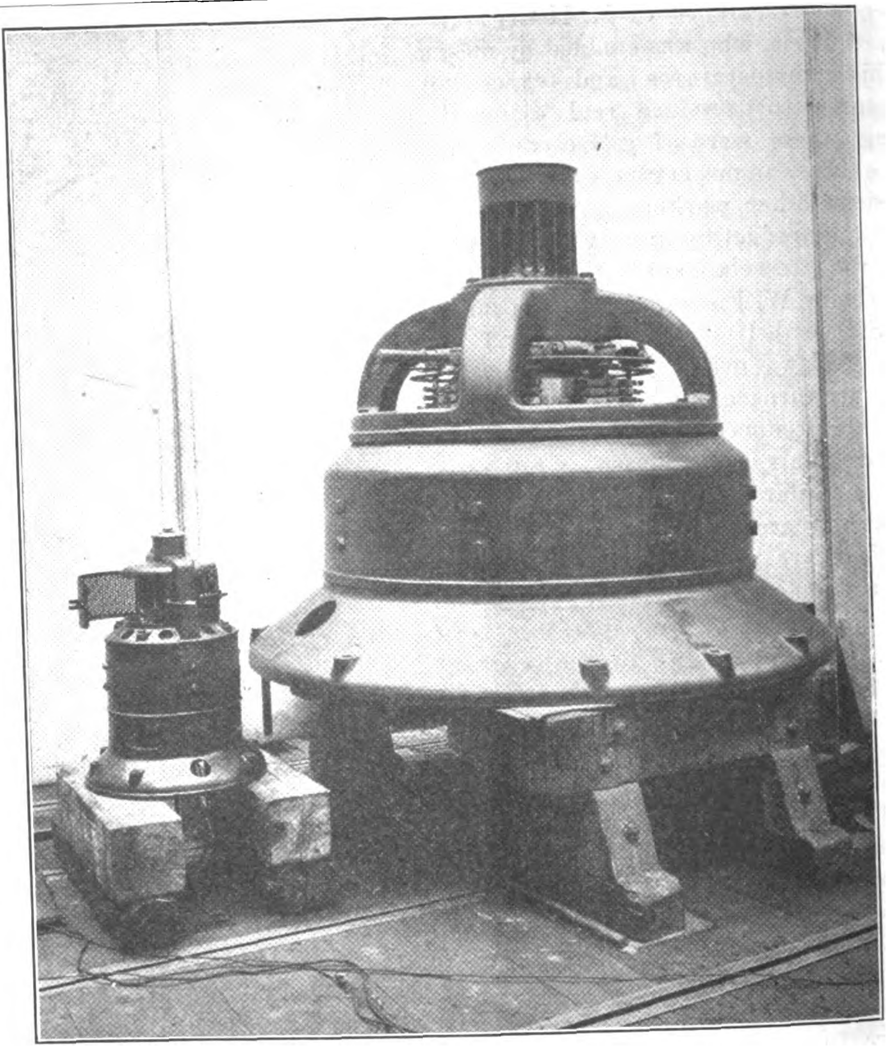
These are the most successful attempts to manufacture diamonds by the electric furnace method that have ever been made, and the diamonds though small are apparently of excellent quality. Although no stones that are large enough to be of commercial value have yet been prepared the problem is of fascinating interest, for it not only points out a method of making diamond powder for grinding purposes, but seems to mark the beginning as well of artificially making real diamonds sufficiently large for adornment.

Different from the electric incandescent furnace the temperature of the arc furnace is very difficult to regulate and in this may lay the secret of diamond manufacture, that is to say, there may be a certain critical temperature to which the graphite must be heated in order that it may crystallize when it is chilled by its contact with the water. As an illustration of the importance of heat regulation on other compounds Mr. Townsend cites the following:

"If a mixture of sand and coke is cautiously heated in an electric resistance furnace a partial reduction of the sand occurs and a product containing silicon, oxygen and carbon, known as "siloxicon" is formed; at a somewhat higher temperature the reduction is complete and there results an amorphous body, having the essential components of carbide of silicon and technically called "white stuff" At a yet higher temperature this amorphous body passes into the crystalline carbide of silicon or "carborundum," a compound approximating in hardness the diamond itself; while at still higher temperatures, approximating that of the arc furnace, this carborundum is broken down, its silicon escapes as a vapor and its carbon remains in the form of graphite.

The effect of high temperature upon reaction is two-fold; in the first place the velocity of the reaction is increased so that chemical charges which at lower temperatures occur slowly, or not at all, take place rapidly or even with explosive violence; in the second place new conditions of equilibrium are established and the chemical elements enter into that combination which under most circumstances sometimes gives rise to compounds not before known. To produce a given result, however, it is usually necessary to work within definite temperature limits and this is most likely



Paris Metropolitan Railway's 130 Hp. Vertical Shaft Pump Motor.

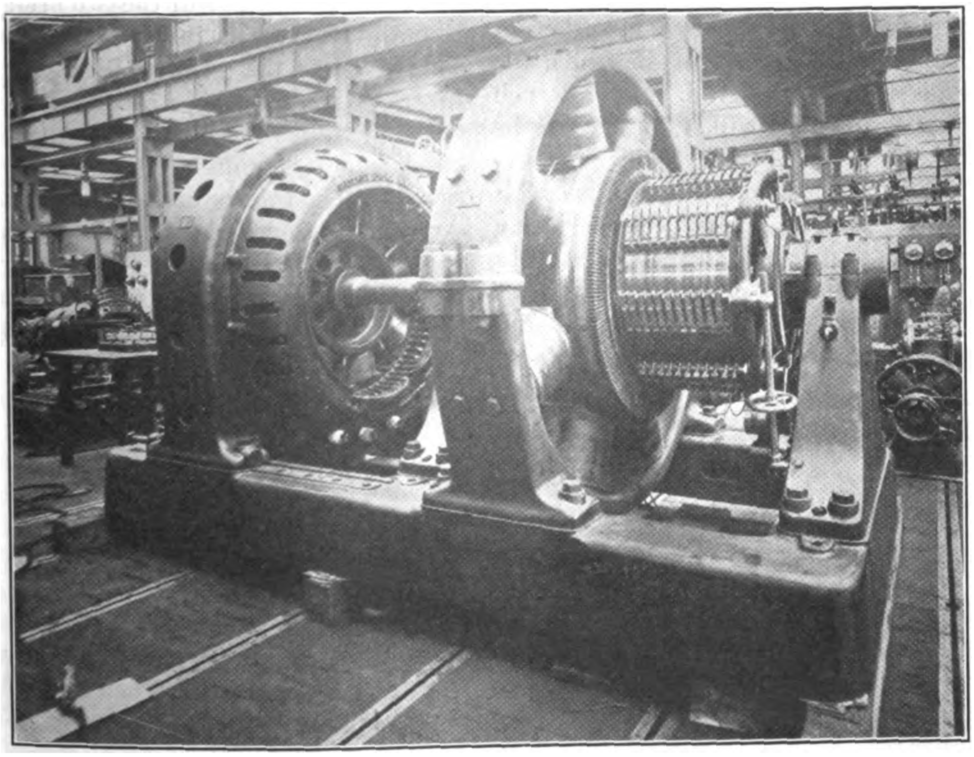
the case of making diamonds in the arc furnace.

In any event it would seem that the goal is not so far distant, and it is extremely probable that continued research will lead to a discovery that will not only greatly simplify the production of diamonds, but what is even more important, will place a far lower value upon them than at present quoted by the "Diamond Trust."

◆

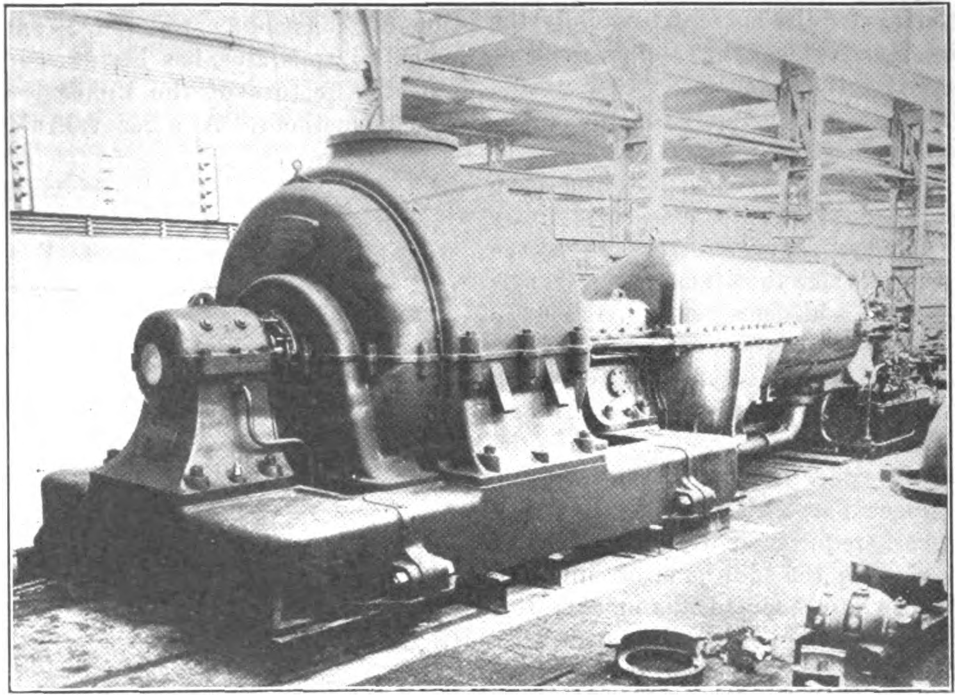
THE NEW TURBINE PLANT OF THE PARIS METROPOLITAN RAILWAY.

Early in January, 1906, another important section of the Paris Metropolitan Underground Electric Railway will be completed. For this and all future sections of this railway power will be drawn from the new power station which has for some time past been erecting at St. Denis, Paris. The original station which has been supplying the system since the year 1900, when electric traction was first used, will not be further enlarged, and its equipment will be continued as at present, aggregating 14,000 kilowatts or thereabouts. The second station has been built for a separate company, the "Societe de Railways et d'Electricite Brussels," formed by the Paris Metropolitan expressly for this purpose, and when the railway and original power station are taken over by the municipality at the termination of the concession, supply of energy, it is assumed, will still have to be obtained from this new company or else satisfactory terms arranged for equitable purchase.



Paris Metropolitan Railway's 375 Kw. Motor Generator.

The new St. Denis station already has two of its large sets running. They are of the Brown-Boveri–Parsons steam turbine, three phase alternator type, each for 5,000 kilowatts, and capable of developing 6,000 kilowatts. When the plant now on order for this undertaking is finished there will be 10 of these 5,000 kw. sets; they run at a speed of 750 revolutions per minute, and each weighs 150 tons. The turbines are built for a steam pressure of 12 atmospheres at the stop valve, and work with steam superheated at a temperature of 300 degs. The lowest vacuum is not to be below per cent. of the barometric pressure.



One of the 10,000 Hp. Steam Turbines for the Paris Metropolitan Railway.

The three-phase alternators will generate at a voltage of 10,000—10,500 volts, and the frequency will be 25 cycles per second.

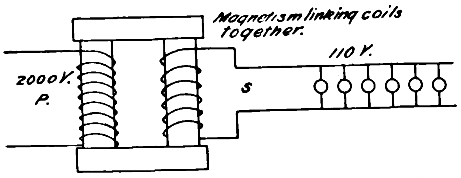
For each unit there is a surface condenser, whose air and circulating pumps are driven by a continuous current motor, and an oil pump (driven by steam) which supplies oil under pressure to the different parts of the turbine. The makers of the plant have guaranteed that the steam consumption shall not exceed 6 8 kgs. per kw. hour, when working under the above conditions. A better result than this is expected, as 6.8 kgs. have repeatedly been obtained with 3,000 kw. turbine sets.

For the first four turbo-generators the exciting current is obtained from a 300 kw. 220 volt continuous current turbo-dynamo, running at 2,700 revolutions per minute, also provided with a surface condenser. Two 375 kw. motor generators act as a reserve for the exciting current, and run also the various pumps for the condensing plants, the feed pumps, etc. The character of machine to supply the current to the six other turbo-alternators has not yet been settled. The accompanying photographs show one of the turbo-alternators, a 375 kw. motor generator, and a 130 hp. vertical shaft pump motor. The first view also illustrates a 7 hp. fire-pump motor.

LIGHT, HEAT AND POWER PRINCIPLES.—XIII.

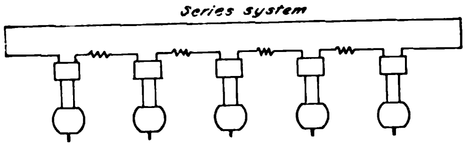
BY NEWTON HARRISON, E. E.

Regulation of Transformer for Lighting.—When the circuits attached to the secondary require current to supply the lamps, it is evident that the only source from which it can indirectly be expected to come is the primary of the transformer. But the electrical energy transmitted to the primary, as has been already shown, is not passed directly into the secondary. Instead it is the means by which the transformer iron is magnetized and demagnetized, and magnetized in the opposite direction. In other words, the magnetism produced in the iron, is the connecting link between the primary and the secondary when the power is either increased or diminished in the secondary. When the secondary, however, requires more current, it is only because the additional circuits connected to it are closed that makes this condition a matter of immediate response to the primary. This coil then permits more electrical energy to pass through it, or to be more explicit, it permits more amperage to enter. But the vital point in the entire process, is one upon which the candle power of the incandescent lamps connected to the circuit of the secondary depends namely, the preservation of the EMF. of the secondary. There is therefore this interlinked system to be considered. First, the readiness of response of the primary to changes of resistance of the secondary, as indicated by multiple lamp circuits being switched in and out. Second, the uniformity of the pressure of the secondary. The fact that a transformer is so constructed that the difference between no load and full load, is the means of causing a perceptible rise and fall in electromotive force of the secondary, is indicative of an absence of harmony in design. The heightened and lowered lamp candle power would be an annoyance only relieved by a reconstruction of the primary, secondary and iron cross-section.

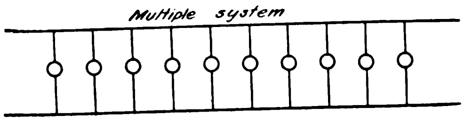


Electricity transformed by means of magnetism.

Constant Current and Constant Potential.—The phrase constant current and constant potential was generally applied to the two great systems of direct current lighting. The constant potential system, has been made the basis of electric lighting by alternating currents as well as direct. In addition a system has been devised, by means of which a constant current is preserved in an alternating circuit as well. The broad classification of constant current and constant potential apparatus, has been the distinguishing feature of the lighting done by such methods. As a general rule, the distinction is made more with reference to the lighting than the power. In this respect it may be added that the use of a constant potential is imperative in all cases where the ordinary incandescent lamp is employed. On the other hand, the arc lamp is the foundation of the division in the electric lighting methods, though both constant current and constant potential lamps are in vogue. The same may be said to a limited extent of the incandescent lamp. There is a method of lighting by incandescents in which the voltage is not preserved, as in all such systems as are in ordinary use. On the contrary, attention is only paid to the preservation of a constant current, and this is the point of similarity between it and a constant current arc lamp system. In either case, the value of the current is limited, the same class of apparatus supplying a constant current to the arc lamp can and has been used to supply a constant current to incandescents. The difference, however, is found in the pressure needed in the two instances for the different lamps. The constant current incandescent, does not require the same voltage as the constant current arc lamp. For instance, in a 1,000 volt circuit of arcs and incandescents, the number of arcs would be, with open globe lamps at least 20; whereas with incandescents the number of lamps would be from 50 to 100.

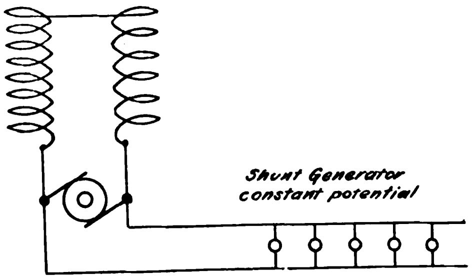


Constant current system.



Constant potential system.

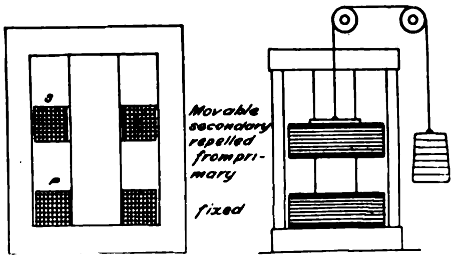
Constant Current Transformers.—In a transformer of this type the ordinary relationship between the electromotive forces of the primary and secondary are not preserved. Instead certain features are introduced for the purpose of sustaining a relationship of which the outcome is a constant current. It is necessary in such a case, however, to preserve a constant electromotive force at the terminals of the primary coil. A system developed with this fundamental idea as a basis, can be best understood as a series system of lighting. In the ordinary transformer, the primary receives a given pressure; the current meets with a certain reactance, and in consequence only an amount of current passes into the primary able to do the work the secondary imposes upon it. But in all such cases, both the primary and secondary coils are in a fixed position. Not only is this true, but the two pressures are fixed in ratio throughout the process. This, however, is the point of difference between the constant potential and the constant current transformer. In the constant current transformer the primary is fixed in position, but the secondary is movable. In addition, the ratio of the two pressures is not preserved as in the former case. This presents the general idea: a transformer with a movable secondary and a ratio of values so crystallized that only the constant current relationship is preserved. The theory underlying this construction is that a high inductance in the primary and secondary coils, but a relatively low mutual induction between them, will be the means of securing constant current in the secondary. Practical features of design dependent upon these ideas, assumed the form of a transformer with a fixed primary as stated, and a movable secondary coil. The core of the secondary, held in common by the primary as well, is long enough to permit the motion of the secondary when necessary. This motion is due to the repulsion which necessarily occurs between inductively related circuits. It is to be expected, as may be discovered by a citation of Lenz's law: That in all cases of electro magnetic induction, the induced currents have such a direction that their reaction tends to stop the motion which produced them. In other words, the coil of the secondary is free to move, and in consequence when the current in it is very strong, the reaction is great and the coil is repelled magnetically. When the current in the



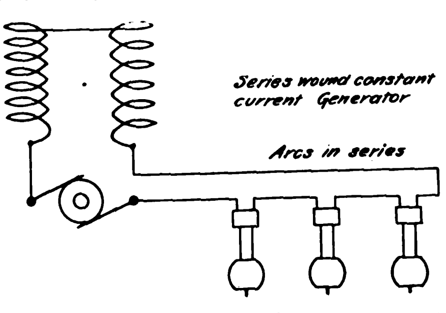
Direct current constant potential system.

secondary is weak the repulsion is not so much in evidence, and in consequence the coils practically rest upon each other. Counterbalancing weights are used, capable of adjustment, by means of which the secondary current is not only preserved at a constant value, but its value may be regulated to represent a certain amount. The degree of repulsion between the coils is not so great that they would of themselves be able to move against great friction. For this reason the two coils are so situated that while one is fixed the other is able to move freely up and down by the aid of a lever and weight system as illustrated. The principle of regulation is readily understood by a consideration of the requirements outside. These are as follows: When a new lamp is added to a series circuit the resistance of the circuit increases. This means less current in the circuit and in consequence less current in the secondary coil. When there is less current in the secondary there is less repulsion between it and the primary coil. In consequence of this the secondary approaches nearer the primary, more current therefore flows through the secondary and more EMF. The effect of this is to repel the secondary to a position where it is able to give to the circuit enough pressure to keep all the lamps burning and enough to fall within the requirements of its being constant. In transformers of the constant current type of large size the primary is composed of two coils, situated above and below. In addition there are two secondaries free to move as in the smaller size, but their movement is both downward and upward respectively. The primaries situated above and below are fixed in position, but the secondaries move in the one case upward to the upper primary, and in the other case downward to the lower primary. In other words, the two secondaries move in opposite directions to each other when the transformer is in operation. This feature has been made use of, to enable the two coils to so affect each other that the regulation for constant current is made without any counterbalancing weights. The series generator for arc lighting is also supplied with automatic means, of an electro-mechanical nature for the preservation of a constant current. But the fact that in one case the current is made constant in a transformer, and in the other case in a generator, naturally calls for a distinct difference between them as pieces of operating mechanism.

Constant Current from a Direct Current Generator.—In a direct current generator, the armature revolves between the poles which produce the magnetic field, and is therefore the source of the EMF. In this respect, the comparison might be instituted of the fields acting in the capacity of a primary, and the armature as a secondary. But this would be only for the purpose of showing that the armature is moved, because unless it is no EMF. can be produced. By this is meant that in the alternating current apparatus, to which reference has been made, the current itself is moving and therefore supplies the basis for inductive action. If the direct current generator were so constructed that its field frame were laminated, then the passage of an alternating current through it would be the means of developing an alternating current in the armature. In this respect the generator becomes a transformer. But it does not belong to that category except in the sense that it is a transformer of a special type, in which mechanical energy is transformed into electrical energy. The electromotive force it generates with a constant speed and constant field is also constant, and it is therefore necessary to introduce means for obtaining a current whose constancy is preserved in spite of the fact that the EMF. under these conditions remains the same. The simple practice of shifting the brushes around on the commutator has been found the best method of accomplishing this purpose. The situation then presents itself of a generator, in which every tendency of the armature to develop a stronger current is met by a movement of the brushes which cuts off the higher EMF. from the circuit at that instant. On the other hand, the tendency of the armature to produce less than the necessary quota of current, is met by a movement of the brushes, which increases the EMF. operating and thus restores the current to its normal value. Both of these processes are necessary when the resistance of the outside circuit increases through the introduction of new lamps, or diminishes when lamps are removed from it.

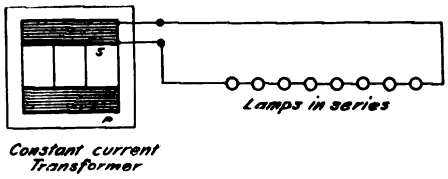


Constant current self-adjusting transformer.



Series system, constant current, direct current system.

Comparison of Constant Current, Constant Potential, Direct and Alternating Current Systems.—The distinguishing features between the various systems employed for supplying arc and incandescent lamps with alternating and direct current can be best understood by a review of the methods involved which may be stated as follows: 1st, Constant potential for incandescent and arc lighting by means of shunt and compound wound generators. Examples of such lighting found in central stations and private installations. 2d, Constant current for arc lighting, generally of high potential and in some scattered instances, of its use for incandescent lighting; the lamps in each case connected in the series. 3d, Constant potential for incandescent lamps and arcs by alternating current. The lamp circuit exactly the same as with direct current, except that the current issues from transformers of various capacities. 4th, Constant current for arc lamps and motors operated by alternating current. In all the cases cited, it must be understood that the electrical energy whether alternating or direct is useful for motors as well. In this respect four classifications also appear, which in a general way cover all applications of electricity to this purpose. 1st, the use of constant potential for shunt, series and differentially wound direct current motors. 2nd, the use of a constant current for series wound direct current motors. 3rd, the use of a constant potential for induction, synchronous and non-synchronous alternating current motors. 4th, the use of a constant current for special constructed motors operated by alternating current. This resume of the situation with respect to light and power is but a brief sketch of the enormous fields each represent in actual practice. The most prominent cases of constant potential systems are found in the use of direct current for street railway work, and arc and incandescent lighting. Constant potential from alternating current



Constant current, alternating system.

mains, is applied in incandescent lighting, and to the running of induction motors of the single, two and three phase type. The recent introduction of the single phase street railway motor is merely an instance of a series wound constant potential motor finding a ready application to a service with a current theoretically well adapted to it, as street railway practice can offer no salient objection to a change in the character of the current as long as the requirements of such practice are fully complied with.

STREET CABLE SYSTEMS.*

BY S. J. WATSON.

(*Concluded from page 332.*)

Wood troughing might be expected to have quite a short life for underground work, but in practice little trouble has been experienced. The materials are inexpensive and easily obtained.

Troughs constructed of stoneware and of cast-iron with wood or porcelain insulators for the cable supports have been used to a considerable extent, a stoneware, or cast-iron covering being provided. Both are suitable materials, although rather rigid, and have given good results.

Another troughing that has been largely used is manufactured of asphalt in lengths of four feet. The joints between lengths are made by means of a hot iron, which renders the material plastic and enables the ends to be formed solid so as to make one continuous length. The cables are laid in the trough and the whole filled up with bitumen. A protective cover of asphalt is then added for protection and ironed down to the sides of the trough. Care should be taken when making the joints between lengths to insure a satisfactory thickness and watertightness of the asphalt so that no moisture can penetrate to the cable which lies on the bottom of the trough without the intervention of bridge pieces. A simple precaution against a bad joint can be made at little expense by inserting a piece of bitumen sheeting about four inches wide between the cable and the trough. This system is reasonable in first cost, the material is flexible, mechanically strong and practically imperishable,

Leaving armored cable out of consideration, it may be said that solid systems are not so convenient to lay in some respects as drawn-in systems. The filling requires the use of a boiler and takes time to melt. Work must be suspended on account of rain to keep moisture out of the trough and avoid the formation of steam bubbles when the bitumen is poured in. A considerable length of street has to be opened out at a time to enable the cables to be laid without frequent joints. Matters such as these do not necessarily increase the cost, but it means additional inconvenience to the public.

CABLES.

For low tension current purposes, whether for a drawn-in or solid system, the cables may be of single, concentric or multicore construction, with hygroscopic or non-hygroscopic insulation, provided with a conducting or non-conducting outer covering.

The first cost of a concentric or multicore system will be less than the equivalent in single cables on account of the greater compactness of the set of cables and the less expensive pipe or trough required when laying. Jointing is, however, much more difficult and costly to carry out, and necessitates the cutting off of the supply while the work is being done.

When such care and attention is given to obtain continuity in the supply, concentric or multicore construction does not appear to offer the minimum of risk, necessitating, as it does, that conductors of opposite polarity will only be separated by an eighth of an inch or slightly more of insulating material, which is invariably paper and particularly susceptible to moisture. Faults are sure to occur sooner or later, and will damage quite a long length of this type of cable, be violent in its results, and probably cut off a portion, if not the whole, of the area supplied.

A more reliable system is obtained by using single cables drawn into separate ways of a conduit or laid spaced apart on a solid system. Each cable is then unaffected by its neighbor's breakdowns.

The most important materials used for insulation are vulcanized rubber, vulcanized bitumen, or bitumen compounds, impregnated fiber and impregnated paper.

Vulcanized rubber is now rarely adopted for street mains, the first cost and the maintenance due to the want of permanence in its insulating properties renders it prohibitive. Could these defects be overcome by manufacturers there is not the slightest doubt it would again come into general use, as high insulation is obtained with a thin coating, which makes the cable of less weight and bulk, and the material is not easily damaged by mechanical means.

The choice is, therefore, between vulcanized bitumen, which does not require an outer watertight covering, and impregnated fiber or paper, which must be provided with a lead or other waterproof protection.

For a solid system no advantage is to be gained by using a lead-covered cable when bitumen non-lead-covered can be obtained at about the same cost.

It is more difficult to choose between lead and bitumen for a draw-in system. Excellent results are obtained with both. Lead-covered have been most successful when drawn into iron pipes, but have given trouble in some instances when used in stoneware, probably due to a deleterious action between the salts used for glazing the stoneware and the lead covering.

The principal defect of all insulation containing a large proportion of bitumen is the liability of the conductors to decentralize on account of the comparatively soft nature of the material. Many faults have undoubtedly arisen from this cause, but manufacturers have given a good deal of attention to the question, and the bitumen now obtainable does not soften at normal temperatures. Isolated cases will, however, occur where, for instance, a cable duct or trough is laid in close proximity to a hot water or steam pipe drain from a house or works to the main sewer in the street.

A leadless cable, whether laid solid or drawn into a conduit of an insulating nature, rarely gives a serious fault without warning even although the insulation is badly damaged, a leakage can consequently be localized and repaired at the most suitable time without inconvenience to consumers.

Much has been said at different times on the question of earthing the lead covering of cables, and it undoubtedly requires treating with caution.

Before the advent of earth return tramway systems no necessity existed for the earthing of all lead coverings and bonding across joint boxes, etc., but owing to the deterioration of the lead in some localities it has now become the general practice to do so. Where long lengths of cable run parallel with the tramway track and are connected direct with the generating or sub-station, it is doubtless a wise precaution to take, but in the event of a fault on the cable developing to a short circuit damage may be done to the covering of all the cables in the immediate vicinity of the fault owing to the relatively poor conductivity of the lead compared with the copper and result in further breakdowns in the near future.

---

*Abstract of paper read before the Institution of Electrical Engineers Manchester, Eng., November 28, 1905.

The best method would be to earth at frequent intervals through a fuse with a resistance in parallel as was suggested by a well-known cable company some years ago. If this is done electrolytic action will not take place, and any serious leakage on the cable is reduced to a safe limit. Such an arrangement, although effective, would probably be expensive in first cost and in upkeep.

It is, perhaps, unwise to attempt to forecast what developments in materials for street work may occur, but with present day knowledge it is difficult to see how the cost of underground work can be appreciably reduced in the near future.

The three necessaries are conductors, insulation, and adequate mechanical protection. To substitute any known conductor for copper will increase the bulk and add to the cost of insulation and protection. Higher pressures than those at present allowed on consumers' premises, even if desirable, which is doubtful, would reduce the weight of copper but increase the insulation. The mechanical protection must be provided.

The most encouraging direction for improvement appears to lie in the use of a mechanically strong insulating and absolutely watertight duct or trough, so that bare copper rod or tape can be used, surrounded with a suitable filling. The expense of stranding conductor and of cable insulation, which is at present considerable, will then be saved. The materials at present on the market most suitable for the purpose suggested are the asphalt trough and the patent fibrous material already alluded to as being used for the construction of pipes for drawing-in purposes.

THE MADISON SQUARE ELECTRICAL EXHIBITION.

The first New York annual electric show is now in full swing at the Madison Square Garden, and the exhibits, which are many and varied, cover pretty nearly everything in which electricity can be used, be it the lighting of a coal-oil lamp by a diminutive dry cell, or a wheel of fire by a gigantic oscillator.

A trip around the amphitheatre reveals, of course, many of our old exposition friends and incidentally several new ones, but all are interesting and so arranged that the layman and the technician must rub elbows at every step, for the simple and the complex are placed in alternate booths, and whether this was accidental or planned, it is an excellent idea, for while the former are asking questions the latter are always at hand to answer them.

Among the more novel and recent features of the exhibition may be cited the electric chimes. Everyone is familiar with the grand old Westminster chimes first played by the large clocks in the tower of that famous old abbey, but long since reproduced mechanically by small mantel clocks. The words and music of this chime were composed by Dr. Crotch, in the year 1793; it is known the world over, and when heard never fails to inspire mankind. Now a Maiden Lane firm has applied electricity to the chime clock, and by its application they have succeeded in reproducing the true Westminster chimes, eliminating all the old complicated apparatus, and in consequence bringing it down to a basis where it is compact and simple, and what is especially advantageous it may be operated at any distance from the timepiece proper and mechanically independent of it. Some of the more expensive chimes are fitted with resonators accurately tuned in unison with the bells, giving rich and musical tones and a much greater volume of sound.

Near the center of the auditorium amid the thousands of incandescent lights are a dozen arc lamps that are absolutely new in this country; they are extraordinarily dazzling, developing about 4,000 candle power as against 1,200 candle power of the ordinary arc light, both consuming an equal amount of current. Those are the much talked of Siemens flame arc effect lamps. The lamps produce a golden yellow, a red, or a brilliant white (Edelweiss) light according to the carbons used, which are impregnated with foreign substances. They have created quite a sensation in lighting circles all over the world and are manufactured by the celebrated Siemans concern of Berlin, Germany.

Air-cooled electric drills amaze many of the sightseers who were not familiar with the use of high feed steels. These drills are adaptable to a wide range of usefulness, and as they are portable they can be used wherever drilling or boring is necessary. One of the new types is called a "tri-motor drill," and has embodied in its construction some clever ideas that are of value to the electrical worker. In this drill three motors are located in a single housing and by means of a new winding for the field coils, which insures the running of each and every motor at the same speed; through a unique method of gearing that has been adapted the makers have been enabled to produce the most powerful portable electric drill ever built, and have at the same time kept down the weight to a point where it is not objectionable.

Of the larger devices shown there is a safety electric elevator that is safe, a new block signal system for preventing collisions on electrified roads, a novel car-lighting system operated by the axis of the car when the train is in motion and by an auxiliary storage battery when at rest, while, finally, the Street Cleaning Department of New York City has on exhibition a model of a lighting plant operated by a refuse incinerator. The practical incinerator after which it is patented, is located near the Williamsburg Bridge, and the useful energy generated from the worthless refuse serves to light the great bridge.

Formerly refuse of all kinds was loaded on scows, when these were towed out to sea beyond the three mile limit and then dumped. The garbage cannot be so utilized, but the dry refuse consisting of waste paper and wood from boxes and crates, packing material, etc., and which has heretofore been charged for, by those who had the contract of towing and disposing of it, a certain rate by the cubic yard, is burned, effecting a very material saving The heat thus evolved is used for the generation of electricity, and in this way another saving is effected. From the cars on which it is loaded, the refuse is transferred into great hoppers where it is carried by endless belts to the furnaces below.

The telegraphone for reproducing and recording articulate speech and other audible sounds, the theatrophone connecting different theatres of New York and Brooklyn with the telephone booth at Madison Square Garden, enables 12 or 20 auditors at the latter place to hear what is going on in the former, and the wireless telegraph for sending and receiving messages to incoming and outgoing steamers are prominently in evidence.

An exceedingly pleasing feature is the demonstration of high frequency and high potential currents given in the hall of the first balcony by Prof. Ovington. There are numerous experiments given, and these appeal to all classes of visitors, for those not versed in the technique of the art find enjoyment in being mystified at the strange performance of what they are told is a manifestation of electricity, while those who are acquainted with the underlying principles of the phenomena, find many new and intricate phases of oscillatory discharges to solve. One of Prof. Ovington's displays, perhaps more spectacular than the others, is called the "fountain of fire," and to produce this effect a giant oscillator is set in action to its full capacity. When an enormous amount of energy is radiated into the surrounding ether, great tongues of electric flame blaze upward and bridge the air-gaps between the terminals, while brilliant streamers issue on all sides of the exposed metal parts of the apparatus.

A LONDON 10,000 VOLT THREE-PHASE INSTALLATION.

(From our London Correspondent.)

The big power station of the Charing Cross & City Company at Bow, four miles from the city of London, has been more or less a mystery-box ever since it commenced working. We suppose there is hardly another generating station in London about which electrical engineers have been allowed to know so little. The heavy curtain of secrecy has, however, now been flung aside by the company's own engineer, Mr. W. H. Patchell, who has gratified the natural curiosity of engineers by reading an elaborate account of his station and its equipment before the London Institution of Electrical Engineers, of which he is a vice-president, on December 7th.

The Charing Cross Company built this station for the purpose of supplying energy in the city area in competition with the old-established City of London Co. It already had its works supplying the western district, but when it was allowed to become a rival in the city area, it resolved to equip a big station four miles outside the area of supply—at Bow—from whence it would meet the needs of the city, and at the same time supplement its existing stations in dealing with the western area. The old stations gave a direct current supply, but at Bow a three-phase installation was put down.

In designing his station Mr. Patchell arranged for the highest pressure that could then be directly generated by the machines and used by the motors, as he was anxious to eliminate the complication of static transformers and to save the extra space and switch gear necessitated by them. A 10,000 voltage, and a periodicity of 50 cycles per second were chosen.

The boilers are of the Hornsby "Upright" type, and a novelty in connection with these consists in the arrangement, for the larger boilers, of a grate in the ordinary way at the front, and another at right angles to it, which can be fired from the side. We understand that these second grates have proved to be of enormous benefit when sudden fog or a thunderstorm has called for an extra supply of steam at very short notice. The ashpits of the two grates are quite separate and are provided with the usual doors. At times of light load the boilers are fired from the front only, and the doors in connection with the side grates are all closed. A little dust falls on the bars at the back, which are not otherwise protected, but do not suffer from the high temperature to which they are exposed. As soon as the demand arises coal is thrown on the side grates, the ashpit doors opened, and the extra fires are got away with surprising rapidity. Each boiler has its own McPhail & Simpson superheater.

Economizers are not used so far, because it was decided that, except in times of top load, the large heating surface available in the boilers would render the necessity of such very doubtful; provision, however, has been made for their addition later should they prove desirable.

The generating plant includes two 800 kw. Lahmeyer generators driven by Belliss & Morcom three cylinder, triple-expansion, quick revolution inclosed steam engines, exhausting into jet condensers. There are two 1,600 kw. generators driven by horizontal cross-compound engines by Sulzer of Winterthur; and there are also two 4,000 kw. Lahmeyer generators driven by Sulzer vertical three-cylinder compound engines with the high pressure cylinder in the center and a low pressure on each side. A special feature is the adoption of feed-water heaters on all the engines, inserted between the low pressure cylinder and the jet condenser. The Belliss engines are served by separate condensers driven electrically, while the Sulzer engines each have their own duplicate condensers and drive their own air pumps.

The cooling towers have steel circular shells.

There is a continuous current plant provided to supply the energy required for the generator fields, station lighting, and the various motors about the works. It consists of two Belliss three cylinder triple expansion quick revolution engines driving 300 kw. Lahmeyer continuous current 200 volt dynamos; also two 350 kw. motor generators and a Hart storage battery.

Mr. Patchell says that no difficulty whatever has been experienced in paralleling the 800 kw. machines driven by high-speed engines, with the larger machines driven by slow-speed engines.

The 4,000 kw. generators have a fly wheel diameter, over poles, of 25 feet; there are 72 poles; the total weight of each machine is 197 tons; the outside diameter of stator frame is 29 feet 2 inches, and the speed 83.3 revolutions per minute.

The switchboard is arranged in two distinct halves, which may be connected by an emergency switch. The board is practically a three-decker. The resistances for the fields of the machines stand on the main engine-room floor underneath the principal switchboard gallery. The panels carrying the controlling gear are upon the principal gallery. The high tension switches are placed on the upper gallery, and are worked positively from the principal gallery by levers.

Cable-charging gear is provided in the shape of a small motor generator and two transformers with suitable connections, so that it may be used either to run up the cables to working pressure or to test them at 15,000 volts. A three-phase generator is driven by a direct current motor, and produces current at a normal 2,000 volts pressure. The current is then stepped up by a bank of two three-phase oil-transformers, and the pressure is varied by varying the field of the 2,000 volt generator. Special bars and switches are provided in connection with the charging gear, so that a cable may be run up and then put in parallel with other working cables, or a working cable may be taken off the main bars and discharged for testing or other purposes.

At present ten trunk feeder mains leave the Bow generating station; they are all three-core, lead-sheathed, paper cables. Six go to the city area and four to the West End, but means for interconnecting them are provided in the city. The cables are laid on the solid system in steel troughs which are heavily bonded to meet the requirements of the Board of Trade.

There are four sub-stations in the city, each having a motor-generator and battery plant. The Fenchurch Street sub-station is typical, and its buildings are erected for accommodating motor-generator plant of 8,400 kw. capacity, and battery plant of 1,600 kw. on a four-hour rating.

The distributors and feeders in the two districts are paper insulated, lead-covered cables laid on the solid system. Each feeder is provided with an automatic cut-out in the sub-station and the distributing networks supplied by separate feeders are interconnected through inclosed type fuses.

New York Electrical Society.

The 255th meeting of the Society will be held at the American Institute, 19 West 44th street this (Wednesday) evening, December 20, at 8 o'clock.

Mr. J. M. Waldron, the signal engineer of the Interborough Rapid Transit Company, will deliver a lecture on "The Signal System of the New York Subway."

In view of the magnitude of the underground railway system of New York, the density of the passenger traffic, the frequency of the trains and the very high speed maintained, the importance of the subject appeals to every one interested in the problem of transportation and in the distribution of the population of large cities. Mr. Waldron will discuss why it was necessary to install a block signaling system; the selection of a system; the power distribution; the alternating current track circuit; the alternating current relay; the mechanism of the signal; the automatic train stop; the air supply and distribution; the interlocking plants, and the practical operation of the system.

Gift to Princeton.

By the will of Dr. J. S. Sayre, which the Missouri Supreme Court has declared valid, $40,000 has been made available for the endowment of fellowships in applied chemistry and electricity to Princeton College.

Copper Prices.

The Boston "Engineering and Mining Journal" appears to have revised its copper prices. It now quotes the metal at 18¾ cents for both lake and electrolytic. Its average price for the metal for the month of December will be watched with interest, for that will be the price which the Old Dominion, Shannon, United Copper and Granby companies will receive for all copper sold this month.

Four Street Railway Systems to be Incorporated.

Pittsburg and Washington, Pa., capitalists will on January 3 make application for charters for four street railway systems, which, it is intended, will connect towns along the Monongahela River with Wellsburg, on the Ohio River. The four companies are to be known as the Coal Center Electric Company, the West Middletown Electric Railway Company, the Washington & Brownsville Street Railway Company, and the Independence Street Railway Company. The companies will be incorporated with only nominal capital, but later on it will be increased to $500,000 each.

Big Electric Contract Let.

A Pittsburg dispatch to the New York "Tribune" says: "The General Electric Company has obtained the contract for equipping the Atlantic City branch of the Pennsylvania Railroad to be operated by electricity. The Westinghouse interests refused to enter into competition with the General Electric at the price named by the New York company. The Westinghouse interests permitted the contract to go by default, and it is figured that at the price of material and labor the General Electric Company stands to lose about $1,500,000, according to the experts of Western Pennsylvania. The contract is for $3,000,000."

Editor of the Question Box.

President Blood has appointed Mr. Paul Lupke, superintendent of the Trenton Division of the Public Service Corporation of New Jersey, editor of the Question Box for the twenty-ninth convention of the Electric Light Association, to be held next May or June. Mr. Lupke has been from the first one of the most enthusiastic and close students of the Question Box, and is a firm believer in its value to central stations. He is himself a thorough engineer, and will undoubtedly make this year's Question Box the equal, at least, of its predecessors.

Hartford Electrical Society Election.

The Hartford (Conn.) Electrical Society, at its recent semi-annual meeting, elected the following officers:

President—Prof. Henry A. Perkins.
Vice-President—Charles A. Hovey.
Recording Secretary—A. G. Steele.
Financial Secretary—S. W. Harney.
Treasurer—Frederick C. Hedrick.
Lecturer—T. H. Day.

"Electric Light and Power Economics," will be the subject of a lecture by Prof. Perkins before the Society tomorrow evening, December 21.

Keystone Telephone Certificates Listed.

There has been listed $2,750,000 of the Keystone Telephone Company engraved stock trust certificates, issued against a like amount of common stock of the company deposited with the Union Trust Company under the terms of the trust agreement of July 1, 1905. These certificates are countersigned and registered by the Provident Life & Trust Company and are transferable at the office of the Union Trust Company, Philadelphia, agent for the voting trustees.

ELECTRICAL PATENT RECORD

LETTERS PATENT ISSUED DEC. 12, 1905.

Electric Railways and Appliances.

806,867. Trolley-Contact. Ira J. Bradshaw, Waukegan, Ill., assignor of one-half to Jacob J. Dietmeyer, same place. Filed Sept. 1, 1905.

807,029. System of Electric Railways. Joseph H. Hoadley, New York City. Filed Sept. 16, 1904.

807,089. Electrically-Driven Suspended Railway. Rudolf Pfaffenbach, Leipsic, and Hermann Muller, Leipsic-Gohlis, Germany. Filed Jan 13, 1904.

807,152. Car-Fender. Eli Campanari, New York City. Filed Aug. 11, 1905,

807,199. Magnet-Controlled Third-Rail System. Henry J. Palmer, Philadelphia, Pa., assignor of one-half to Max Bielman, New York City. Filed Oct. 3, 1904.

Electrical Machinery and Apparatus.

806,777. Controlling Means for Electric Motors. Chas. M. Clark, South Orange, N. J. Filed July 7, 1903.

806,782. Magnetic Clutch. George A. Damon, Chicago, Ill., assignor to the Arnold Magnetic Clutch Company, Milwaukee, Wis. Filed Feb 21, 1903. Renewed Dec. 7, 1903.

806,789. Joint for Electric Conductors. Austin Fleeger, Chicora, Pa. Filed May 3, 1905.

806,942. Electric Time-Lock. John T. Van Dillen, St. Louis, Mo. Filed Aug. 17, 1904.

807,017. Electric Time-Switch. Milton T. Campbell Indianapolis, Ind., assignor of one-half to John C. Ertel, same place. Filed June 5, 1905.

807,051. Electric Attachment Plug. Frederick F. Strong, Boston, Mass. Filed April 3, 1905.

807,053. Switch-Signal. John C. Wigman, Greenbay, Wis. Filed April 6, 1905.

807.263. Junction-Box for Electrical Conductors. Edwin T. Greenfield, Monticello, N. Y. Filed June 21, 1904

807,270. Thermal Cut-out for Electric Conductors. Bryson D. Horton, Detroit, Mich., assignor to the Horton-Morehouse Company, same place. Filed March 13, 1905.

807,390. Radiator and Coil. John H. Lindsay, New York City, assignor of one-half to Frank Dobson, same place. Filed March 19, 1904.

Telephones and Telephone Apparatus

806,790. Telephone Bracket. Henry F. Foersterling, St. Louis, Mo. Filed March 6, 1905.

806,950. Selective System for Party-Line Telephones. William M. Bruce, Jr., Springfield, O., assignor of one-third to James S. Bratley, Jr., Wauseon, O., and one-third to Charles D. Juvenal, Springfield, O. Filed April 3, 1905.

807,235. Alarm and Telephone System. Garrison Babcock. Chicago, Ill. Filed Dec. 14, 1903.

807,316. Telephone System. Robert H. Polk, Birmingham, Ala. Filed Jan. 19, 1904.

Miscellaneous.

806,769. Adjustable Support for Telegraph Line Wires. Jasper N. Bell, Stratford, Ia. Filed Dec. 23, 1904.

806,801. Telegraph Repeater. Oscar C. Greene, St. Paul, Minn., and Charles H. Gaunt, Topeka, Kan. Filed April 28, 1902.

806,853. Manufacture of Vapor Electric Apparatus. Percy H. Thomas, East Orange, N. J., assignor to the Cooper Hewitt Electric Company, New York City. Filed Feb. 12, 1904,

806,894. Telegraphic Repeater. Stephen D. Field, Stockbridge, Mass., assignor to John J. Ghegan, Newark, N. J. Filed Dec. 31, 1904.

806,887. Insulator-Pin. Walter T. Goddard, Victor, N. Y., assignor to the Locke Insulator Manufacturing Company, Victor, N. Y. Filed May 24, 1905.

800,891. Telegraphic Apparatus. Melville A. Hawley and William L. Rhoads, St. Louis, Mo.; said Rhoads assignor to said Hawley. Filed April 3, 1905.

806,935. Insulating Wire-Support. John A. Sullivan, Cleveland, O., assignor of one-half to I. F. Helper, same place. Filed Dec. 15, 1904.

806,953. Electric Signaling Apparatus. Louis A. Codere and Alphonse E. Croquette, Sherbrooke, Can. Filed Nov. 25, 1904.

806,966. Wireless Telegraph System. Lee De Forest, New York City. Filed Jan. 25. 1904. Renewed Oct. 14. 1905.

807 307. Insulator. Louis McCarthy, Boston, Mass. Filed Feb. 18, 1904.

THE TELEPHONE WORLD.

Meeting of West Virginia Independents.

At a recent meeting of the executive committee of the Independent Telephone Association of West Virginia, held in the office of W. C. Handlan, manager of the National Telephone Company in Wheeling, it was decided to hold the first meeting of the association at the Chancellor Hotel of Parkersburg, on February 22 and 23, 1906, at which time the representatives of all the Independent telephone companies of the State and also from other States will be in attendance.

The object of the coming meeting is to bring all of these who do not now belong to the association into it and bring harmony among the Independents so that all may fight in harmony in the battle against the competing company.

The executive committee members at the meeting were General Manager A. E. Davis, of the West Virginia Telephone Company of Parkersburg; J. Walter Barnes, general manager of the Consolidated Telephone Company of Fairmont, and W. C. Handlan, of the National Telephone Company of Wheeling.

The St. Joseph Valley Telephone Company was lately formed to do business in Elkhart, La Porte, St. Joseph, La Grange, Steuben, Noble, Kosciusko, Marshall and Starke Counties, Ind., with main offices at South Bend. Its capital stock is $25,000. The directors are: Theodore Thorward and Jerry Donovan, of South Bend, and Martin E. Crow, of Elkhart.

The Southern New England Telephone Company is to build a new exchange in Danbury, Conn., which will be equipped with the common battery system.

The Mt. Zion, Mo., Telephone Company is a new concern incorporated by J. D. Snyder, J. W. Stanton, T. H. Good, J. N. Butler, E. P. Edwards, T. J. Bilderlack and others.

To give better service and cheaper rates to residents of Solvay, Baldwinsville, Skaneateles and East Syracuse, branch exchanges are soon to be established in those villages by the Central New York Telephone & Telegraph Company.

The Delaware & Atlantic Telegraph & Telephone Company has decided to extend its underground system and has made application to the street and sewer Department to lay conduits in Wilmington.

The Central Telephone & Electric Company of St. Louis, Mo., lately filed a statement to show that it had made an increase in its capital stock from $50,000 to $75.000, all the increase paid. Assets, $105,736.07; liabilities, $25,836.07.

A new company, known as the Courtland Emporia Telephone Company, capitalized at $5,000, has been incorporated in Drewryville, Va., with D. B. Drewry, president, and F. P. Pope, secretary and treasurer.

The Farmington Valley Telephone Company of New Britain, Conn., lately filed a certificate with the State Secretary, certifying to an increase in capital stock from $27,000 to $54,000.

Independents Open New Territory.

New telephone territory is rapidly being opened to Galesburg, Ill., by reason of the expanse of the Independent companies in that section of the State. A short time ago the line between Macomb and Monmouth was opened; soon the new Williamsfield line will be in operation, and it is now but a matter of crossing the Mississippi River when the new Burlington line will be ready for use.

The line between Macomb and Monmouth covers a gap in the network of long distance lines being planned by the Independents and now gives Galesburg excellent service to Macomb as well as intermediate points. The Independent company in Galesburg has been able to reach Macomb before, but the service has not been nearly as satisfactory as it is at present.

The new Williamsfield line will also fill a long felt want. Williamsfield has been on the line heretofore, but the service has been slow and also poor. Now a Williamsfield company is building a trunk line from there to Knoxville, with which Galesburg will be connected and form a trunk line from Galesburg to Williamsfield.

The poles for this line are already being erected and within two weeks the wire will be stretched for the entire distance of 15 miles and the line opened. It will be a trunk line between those places with no intervening station.

When these lines are completed and in running order considerable new telephone territory will be opened to the people, which will be heartily appreciated.

Telephone Merger Under Way.

It is understood that the Keystone Telephone Company, of Philadelphia, Pa., is negotiating for the control of the Eastern Telephone Company, which controls the system in Camden and Gloucester, N. J., has an interest in the Camden & Atlantic City, and owns 40 per cent. in another paying property. If the deal goes through it is said that the Keystone will have control of the territory.

The Inter-county Telephone Company, a new Independent telephone company, of Decatur, Ala., according to a dispatch, has completed its system of lines and is now about ready for business. This company will cover the eastern part of the county, which has never had any telephones. The company will also connect with Huntsville. The capital stock of the company is $20,000, and the officers are: President, C. E. Hodgeboom; vice-president, Gus May; secretary, C. D. Hodgeboom.

James A. Boyd and Charles A. Boyd, of Cambridge City, Ind., owners of the Independent Telephone Exchange there, have purchased the Hagerstown Independent telephone plant. Nearly 2,000 'phones are on the system, which extends from Losantiville on the north to Connersville on the south.

The Pioneer Telephone Company has purchased the automatic system in Waukomis, Okla., and will make a number of improvements in the local exchange.

Another Independent Company Launched.

Another effort is being made to float an Independent telephone company, which will have its headquarters in this city, and will operate throughout the country. In its prospectus the Great Eastern Telephone Company, as the most recent Independent telephone company is called, offers 50,000 shares of preferred 6 per cent. cumulative preferred stock at par, with which a bonus of 50 shares of common stock will be given for every 100 shares of preferred stock bought.

George R. Bidwell, former Collector of the Port, is one of the directors. He said recently that the Great Eastern Telephone Company was in no way identified with the Finucane telephone enterprise, which sought to raise $15,000,000 by an issue of bonds.

The Great Eastern Telephone Company is said to be a holding company of several Independent concerns. It holds a franchise for a telephone system in New York granted in 1883 to the New York Electric Lines Company, and quotations from the franchise are given. The company also asserts its ownership to a franchise in Brooklyn. Among the other directors are J. F. O. Meyers, J. Van Vechten Olcott, W. C. Adams, George C. Edwards, Edward G. Ward and William H. Stayton.

A deal has recently been consummated by the Independent Union Telephone Company of Albany, N. Y., whereby it secures possession of the Independent telephone company of Herkimer County, which operated a rural line out of the village of Herkimer. The system transferred to the Albany company is located in the towns of Herkimer, German Flatts and Little Falls, and is connected with the Herkimer telephone system. The line extends from that village to the south side of the Mohawk River, thence to Fort Herkimer and Jacksonburg, thence to the north side of the river and eastward. The consideration was said to have been $1,725.

Three telephone companies are struggling for a franchise in Brantford, Ont. The Bell Company desires to hold what it has, an exclusive franchise. The Canadian Machine Company and the Ontario Telephone Company are looking for competitive franchises. The Canadian Machine Company desires a 21 years' agreement, with an option for municipal ownership; prices to be $25 for business and $15 for residence 'phones, and the Ontario company wants a 20 years' franchise at $25 for business and $18 for residence.

James M. Brogan, of Dansville, N.Y., has been appointed by the officials of the Inter-Ocean Telephone Company to manage the affairs of the company in that village.

Many additional telephones have been installed in Wilmington, Del., during the past few months and it is said that there is now a telephone for every 15 inhabitants.

The Quincy, Ill., Long Distance Telephone Company, capitalized at $2,000, has been incorporated by Frank J. Penick, J. R. Pearce and Samuel E. Scott.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Anadarko, Okla.—This city is considering the advisability of voting $5,000 additional bonds for the extension of the electric light service.

Ashland, Ore.—The Ashland Electric Light Company has made a proposition to sell its entire holdings here, including the water rights which the company claims, now in litigation, and also a 20-year lease which it holds with the Condor Power Company, which now supplies the current to the city. The company asks about $60,000. If its proposal is accepted all suits will be dropped and it will withdraw from the city.

Belleville, Kan.—At a recent meeting of the citizens, it was the expression of those present that the city erect a $20,000 electric plant, and run it in connection with the waterworks. There is a company organized here, whose purpose is to erect an electric light plant, and it may be possible that the company and the city council will work together.

East Moline, Ill.—An ordinance was lately submitted to the council by the Central Electric Company providing for a franchise to install a light and power plant in this town, to be in operation in six months. A. A. Woodworth represents the company.

Edgefield, S. C.—At a recent mass meeting, held to discuss the light and water problem, a committee was appointed to get in touch with the principal and best installers of water and electric plant systems. Among the men interested are J. C. Sheppard, A. E. Padgett, Charles E, May, M. P. Wells, W. W. Adams, J. W. Thurmond, J. L. Mims, B. B. Jones, J. M. Cobb and Thomas H. Rainsford.

Eldora, Ia.—John Rath, one of Ackley's most influential and wealthy citizens, has offered his home town the gift of an electric light plant, worth about $15,000, fully equipped and ready for business.

Fredericksburg, Tex.—G. A. Pfell will erect an electric light plant in connection with his cotton gin.

Homestead, Pa.—A newly organized concern, known as the Homestead Light & Power Company with a capitalization of $100,000, has asked for a franchise here. A committee has been formed to procure estimates of the cost of construction and maintenance of an electric light plant.

Laramie, Wyo.—The Union Pacific will install its own electric light plant in the depots, yards, shops and steel mills.

Millersburg, Ia.—The Fairbanks & Morse Electric Company of Chicago, is preparing to put in an electric light plant here.

Montgomery, Ind.—C. W. Slibhard is preparing to erect a new electric lighting plant here.

Port Townsend, Wash.—John Siebenbaum and others have been granted a franchise by the city council to construct an electric light plant, erect poles, string wires and do any and all things necessary to properly operate such a plant.

Richmond, Ind.—At a meeting of the city council last week action was taken toward increasing the capacity of the municipal lighting and power plant. The council has instructed the board to employ an electrical engineer to draw up plans and specifications for the addition of another unit to the plant,

Rutland, Vt.—The electric light plant of this city was recently damaged by fire to the extent of about $5,000.

Salt Lake City, Utah.—Frank Taylor, of this city, has filed an application with the State engineer for 200 feet of water from the Weber River in Summit County, to be used for furnishing electric lighting and power in Oakley.

Savannah, Ga.—This city will probably have a political fight for the control of the electric lighting contract of the city next year that will be like that in Atlanta some years ago. The Savannah Electric Company, which now has the contract for the city lighting, is to be opposed by the Savannah Lighting Company, a new concern. Both sides are said to be getting ready for a battle at the polls next year.

St. Matthews, S. C.—An election will soon be held to vote on the proposed issue of $20,000 of waterworks and electric light bonds.

Syracuse, N. Y.—The Syracuse Electric Light Company has been incorporated with a capital of $100,000. The incorporators are W. Darrone, C. E. Darrone and others.

Tallapoosa, Ga.—This city has voted a $10,000 bond issue for the erection of a new electric light plant.

Victoria, Tex.—The citizens have petitioned the council for an electric light plant.

STREET RAILWAYS.

Auburn, N. Y.—The Mohawk Valley Company, the trolley company of the New York Central Railroad, is preparing plans for the electrical equipment of the Auburn branch from Syracuse to Rochester, utilizing the Rochester & Eastern as far as possible.

Canton, Ill.—Construction of at least one section of the Illinois Central Electric Railroad Company's line will be begun next spring, if the present plans of the board of directors are carried out.

Carmel, Ind.—A company was incorporated at Indianapolis last week to build a traction line from this city to Frankfort through Westfield and Sheridan.

Charter Oak, Ia.—P. F. Piene is in communication with parties who propose to construct a trolley line from Council Bluffs to this place.

Columbus, O.—D. Hood, of this city, is in charge of the preliminary surveys of the Ohio Central Traction Company, which expects to build an electric line from this city to New Lexington.

Greenville, Pa.—Cox Brothers, former citizens of this place, have projected plans to build an electric railway from Ashville to this city.

Magnolia, Ia.—An electric railway is to be built from Missouri Valley to this place. The work of securing the right of way will be commenced at once. The road will tap an exceedingly rich farming country which has no nearby railway outlet. The project is backed by Harrison County capitalists.

Milwaukee, Wis.—The Milwaukee Electric Railway Company is to spend a large sum of money on its system. It will erect a new power station and build two new cross town lines.

Mt. Vernon, O.—A franchise was recently granted the Mt. Vernon Electric Street Railway Company to extend its line into South Vernon.

Ottumwa, Ia.—H. M. Byllesby & Co., of Chicago, lately purchased the stock of the Ottumwa Traction & Light Company, and will make large extensions and improvements.

Syracuse, N. Y.—The feed wire which supplies electricity for the operation of the Solvay line of the Rapid Transit Railway is to be extended for a distance of ¾ of a mile in order to furnish more power at the western end of the road.

POWER PLANTS.

Georgetown, Col.—Upper Clear Creek will soon have another electric power plant, capable of supplying an abundance of power W. E. Renshaw, of Idaho Springs, has entered the field, and expects soon to be in a position to furnish power for mines.

San Bernardino, Cal.—The Hill street power plant of the San Bernardino Electric Company has lately been destroyed by fire, entailing a loss of $65,000.

BIDS WANTED.

Cape Girardeau, Mo.—The Cape Brewery & Ice Company will need electrical equipment.

Elbow Lake, Minn.—Sealed proposals will be received by J. S. Arneson, county auditor, until January 4, 1906, for the furnishing of electric light fixtures for the new Grant County Courthouse. Bids must be accompanied by a certified check in the sum of $100, as an evidence of good faith.

Freeport, Ill.—Sealed bids will be received by the city clerk until 3 o'clock January 2 for lighting this city for a term of five years.

Grand Island, Neb.—The city council will receive bids for electrically lighting this city for a term of one year.

Marshall, Mo.—William H. Black, president of the Misouri Valley College, wants prices on electrical equipment.

Washington, D. C.—The Navy Department through the Bureau of Supplies and Accounts is inviting sealed proposals until January 2, 1906, for furnishing the following electrical material embraced in schedule 286: League Isand Navy Yard, 3,500 incandescent lamps, 5 annunciators, 11,000 feet wire, 6,000 feet lighting wire, 15,000 feet lighting wire, twin conductor; New York Navy Yard, 3,000 feet lighting wire, about 1,000 pounds magnet wire, 550 pounds insulating tape, 50 water-tight bells, 25,000 fuses, 10,000 feet lamp cord, 10 testing generators, 10 voltmeters, 5 sets of engine indicators, 1,000 attachment plugs, 30 telephone headgears and miscellaneous electric supplies. Proposal blanks and detailed information can be obtained on application to the Bureau or to the Navy Pay Office in New York. On January 9 the Bureau will open bids for furnishing the New Orleans naval station with weather-proof wire and electrical supplies, embraced in schedule 290, which can be obtained upon application to the Bureau.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 18½@18⅞c. Lake 18½@18⅞c.; casting, 18@18½c.

The Reading (Pa.) Traction Company has declared a dividend of 75 cents a share, payable January 1.

The annual meeting of the stockholders of the El Paso (Tex.) Electric Company will be held in East Orange, N. J., on January 8.

A Philadelphia Electric director is quoted as saying that the company is earning 7½ per cent. on its capital stock of $10,000,000.

The American Telephone & Telegraph Company's stockholders will meet to-morrow to authorize the issue of $150,000,000 of convertible bonds.

The Brooklyn Rapid Transit Company has applied to the New York Stock Exchange to list $3,042,000 additional first refunding mortgage 4 per cent. bonds of 2002.

The stockholders of the Toledo Railways & Light Company will hold their annual meeting in Toledo, O., on January 18. Books close January 6 and reopen January 19.

Westinghouse interests say that the increase of capital of $4,000,000, to be voted December 23, will be used mainly to build and equip shops needed to increase the output of turbines.

The trustees of the Boston & Worcester Electric Companies have declared a regular semi-annual dividend of $2 per share on the preferred stock, payable January 1 to stockholders of record December 23. Transfer books close December 24 to January 1.

The Boston Stock Exchange has stricken from the unlisted sheet the temporary receipts for stock of the Mexican Telephone Company and has placed on the list 21,190 shares of common and 10,959 shares of preferred stock of the Mexican Telephone & Telegraph Company.

Wall Street is now anticipating a fight between E. H. Harriman and Thomas F. Ryan, which may involve, through the Legislature, the Consolidated Gas Company and the Metropolitan Street Railway Company of New York, in which Mr. Ryan is largely interested.

William A. Read & Co. of New York are offering to investors 1,000 shares of Twin City Rapid Transit Company 7 per cent. cumulative preferred stock to net the investor 4⅝ per cent. This company controls and operates all the electric railways of Minneapolis and St. Paul, and suburban points, in all 325 miles.

S. C. Schenck, of Toledo, O., a heavy stockholder in the Toledo & Indiana Electric Railroad, says that bonds of the road aggregating $1,600,000 have been refused by the New York underwriters and thrown back on the promoters. The cause of the rejection is alleged to be faulty construction of the road.

A circular will be issued to the stockholders of the preferred stock of the Bullock Electric Manufacturing Company within a short time announcing a change in the financial arrangement. Under the present lease of the Bullock Company to the Allis-Chalmers Company the preferred stock is guaranteed for 25 years. Under the new arrangement the Allis-Chalmers Company perpetually guarantees the stock. The issue amounts to about $1,200,000 and is a 6 per cent. cumulative stock. The present certificates will be recalled and new ones issued.

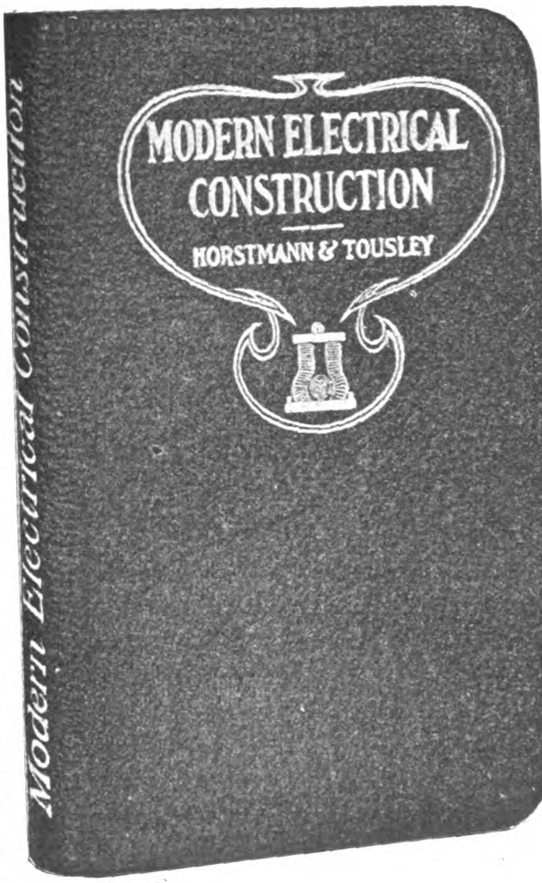
FOR ELECTRICAL WORKERS PUBLISHED.



MODERN ELECTRICAL CONSTRUCTION
HORSTMANN & TOUSLEY
Modern Electrical Construction

Modern Electrical Construction

BY

HORSTMANN & TOUSLEY

This book treats almost entirely of practical electrical work. It uses the "rules and requirements of the National Board of Fire Underwriters" as a text, and explains by numerous cuts and detailed explanations just how the best class of electrical work is installed.

Partial Table of Contents

Arc Lamps and Circuits.
Bell Wiring
Current.
Calculation of Wires.
Constant Current System.
Constant Potential Systems.
Cutouts and Circuit-breakers.
Conductors and Insulators.
Convertible Wiring.
Divided Circuits.
Dynamo Installation.
Electro-motive force.
Electrolysis.
Electric Bells.
Electric Light and Power Circuits.
Fire Hazard.
Fish Work
Grounding of Power Circuits.
Gas Lighting.
High Tension Wiring.
Heating Apparatus.
Inside Wiring
Incandescent Lighting.
Illustrations of Methods of Installing Wires and Apparatus,
Joints in Lead-covered Wires.
Loop System.
Lightning Arresters.
Losses in Wiring. Illustrated by diagrams showing most economical location of cutout centers and losses on differently arranged circuits.
Method of Determining Size of Conduit Necessary for a Number of Wires of Any Size.
Multiple Arc Lamps
Multiple Series System.
Motors.
No Voltage Release.
Nernst Lamps,
Ohms Law.
Outside Wiring.
Personal Hazard on Live Circuits.
Pole Line Construction.
Power.
Practical Hints.
Practical Tables concerning number of wires that can be run in certain conduits; Trade Numbers of Insulators, Screws, Nails, Moulding, etc., to be used with wires of given size,
Resistance.
Resistance Boxes.
Speed Controllers.
Series Arc Lamps.
Switchboards.
Safety Rules.
Telephones.
Three-wire System.

MODERN WIRING DIAGRAMS AND DESCRIPTIONS

A HAND BOOK OF PRACTICAL DIAGRAMS AND INFORMATION FOR ELECTRICAL WORKERS

By HENRY C. HORSTMANN AND VICTOR H. TOUSLEY

THIS GRAND LITTLE VOLUME NOT ONLY TELLS YOU HOW TO DO IT, BUT IT SHOWS YOU.

CONTENTS

	DIAGRAMS		DIAGRAMS
Call and Alarm Circuits	12	Electric Lighting	30
Annunciators	8	Arc Lamps	4
Bells	9	Meters	28
Return Call Annunciators	4	Motors	21
Fire and Burglar Alarm	10	Generators	7
Telephone	7	Compensators	1
Telegraph	8	Switch Boards	8
Gas Lighting by Electricity	4	Ground Detectors	10
Automatic Fire Alarms	1	Storage Batteries	1
Primary Batteries	7	Testing	2
Connecting Up	3	Wheatstone Bridge	3
Miscellaneous Circuits	6	Light	6

Wiring Tables with Illustrations; Trouble, and how to find it; Transformers; Useful Facts, etc.

160 Pages, over 200 Illustrations, Full Leather Binding, Round Corners, Red Edges, Pocket Size 4 x 6
Price, NET $1.50

THOUSANDS OF DOLLARS' worth of information are bound up within the covers of these books. It is only necessary to glance through the index of each to place a high value upon them. The difference between the successful man and the failure is largely knowledge and partly good fortune. But some would say entirely knowledge. For this reason the books of greatest value are those most useful in making a man a thinker, a better worker and a success. Such books are those containing useful knowledge and principles. They are easily procured. A small sum buys both. Begin at once.

THE COPPER HANDBOOK.

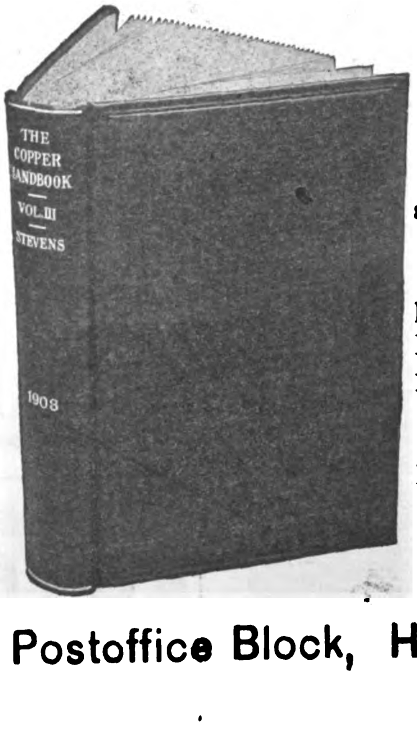
A practical book of nearly a thousand pages, useful to all and necessary to most men engaged in any branch of the copper industry.

Its facts will pass muster with the trained scientist and its language is easily understood by the every-day man.

It is a dozen books in one, covering the History, Uses, Terminology, Geography, Geology, Chemistry, Mineralogy, Metallurgy, Finances and Statistics of Copper.

It gives the plain facts in plain English without fear or favor.

It lists and describes 3,849 copper mines and companies, in all parts of the world, descriptions running from two lines to twelve pages, according to importance of the property.



THE COPPER HANDBOOK
VOL. III
STEVENS
1903

The Copper Handbook is conceded to be the

WORLD'S STANDARD REFERENCE BOOK ON COPPER.

The miner needs the book for the facts it gives him about mines, mining and the metal.

The investor needs the book for the facts it gives him about Mining Investments and Copper Statistics. Hundreds of swindling companies are explained in plain English.

Price is $5 in Buckram, with gilt top, $7.50 in full library morocco. Will be sent fully prepaid, on approval, to any address ordered, and may be returned within a week of receipt if not found fully satisfactory.

EDITORIAL NOTES.

The Year That is Going and the Year That is Coming.

It cannot be denied but that the year about to close has been a prosperous one generally speaking to the electrical fraternity. Business throughout the country in almost every line has been—if not booming—in an exceedingly healthy condition, and as a natural result the electrical manufacturers have gotten their share.

During the year 1905 the war in the Far East has been terminated, which means among other things the opening up in the near future of markets heretofore but little exploited. Japan has been for some time a good customer for electrical machinery, and there is but little doubt but what China will eventually need electrical apparatus, and there is no good reason why it should not be purchased in this country, providing our manufacturers and dealers seek that market in the proper way.

Looking forward, the year 1906 would seem to harbor no commercial cloud of adversity in spite of the unsatisfactory condition of affairs in Russia. In a country such as ours, prosperity or business depression does not depend upon the internal doings of a nation thousands of miles away.

* * *

Objection to Searchlights on Trolley Cars.

Interurban lines, and those denominated as cross-country lines, often have routes to cover which introduce a decided element of danger through the possibility of collisions or worse. The oil lamp, originally employed as a headlight, gave way to the incandescent lamp. The light from this was not strong, neither was it very far reaching When the arc lamp attained that degree of excellence which made its mechanism a familiar thing to manufacturers, a successful effort was made to adapt it to moving vehicles, such as locomotives and electric cars. In both these instances its adaptation proved an unqualified success.

The steam locomotive, with its powerful space annihilating beam could light its way a thousand or more feet in advance. The sense of security this gives to engineers can be readily appreciated, when it is remembered that a feeling of apprehension is never absent from those fully alive to the responsibilities of their position. In fact this is the only menace to safe travel—the darkness of the track. The train plunging ahead from darkness into darkness, gives the engineer but a momentary glimpse of the track. We give more in lives and money each year, as a tribute to the moloch of railroads, than was ever required by the bloodiest battles of the civil war. This is true as well of the electric traction companies operating within and beyond the city limits. In many cities the damages paid through loss of life and bodily injuries represent yearly sums that range from a million dollars to hundreds of thousands in the said cities respectively.

When we hear of any objections therefore to the use of plenty of light by vehicles traveling on the public highways it sounds like irrationalism of the worst type. In arguing this question the "Sun" states: "The trolley companies plead the safety of the public—the longer the radius of light the less the danger of collision." We think they are right, though the same publication subsequently derides the altruism of the traction companies. It believes the struggle for the highways between the people accustomed to using them and the electric roads which are hastily swallowing the profits once made by the steam lines is the correct view to take. It furthermore believes that keen competition has led the electrical roads to reach speeds of 20, 30 and 40 miles an hour, hence the powerful warning searchlight. Suspicion and pessimism are frequently the dominant notes in the "Sun," though couched in the choicest of phraseology. The fact of the matter is, that the people are glad to ride in the equally swift and considerably cheaper electric car wherever it parallels the steam road. Cyclists, automobilists and that historic class of sleepy-headed old farmers plodding along the track with their loaded teams express in their objections, what can only be rightly regarded as a lack of consideration for thousands of their fellow men. The cyclists and automobilists ought to remain very quiet as regards this matter. The "ploughman that homeward plods his weary way," as Gray puts it, need not find it in front of a hustling trolley car filled with equally weary people. Satire from the press regarding the acts of corporations seems to have degenerated into criticism of good acts as well as bad. As a sample of common sense, it seems that it would be difficult to find a better example than that of brightly lighting a railroad track as far in advance as possible of the moving car.

* * *

Art Fixtures in Electric Illumination.

The poetic and the prosaic are not always so closely related as in the instance of the influence of a practical system of electric lighting upon the design of chandeliers and fixtures. In this industry the incandescent and arc lamp have been made the basis of a series of artistic inventions, upon which crystallized art principles now rest. Large office building vestibules and halls, finished according to Greek or Pompeian styles of interior decoration, are illuminated by fixtures which betray the correct impression of lighting done in those days; though the light itself is provided by incandescent lamps whose ready adjustment to interpreted art ideas enables designers to carry out their plans in all essential details. Art fixtures thus represent today what they did not and could not represent twenty years ago. The ease with which concealed wires are so situated within the foliage or figure design that the art effect is enhanced by the light seeming to emanate from the thing itself, is one of the triumphs of modern art illumination. The large manufacturers of electroliers and artistically designed wall and ceiling fixtures, have long since realized that the general use of electricity is the one and only means by which these art ideas have been applied to interior design. Magnificent results have been obtained in the fine hotels and apartment houses as well as the office buildings thus equipped. This joining of interests has proved an effective spur to the development of lighting as well as the art ideals it now crystallizes.

◆

The directors of the Cleveland (O.) Electric Railway Company have raised the wages of more than 2,000 motormen and conductors one cent an hour.

◆

An assistant of Prof. Ramsay at the University College, London, claims to have found a new radioactive element. It is said that the new substance is as nearly as active as radium and is a constituent of thorium, used in the manufacture of gas mantles. The substance has been named radio-thorium.

◆

President Sullivan, of the Massachusetts Electric Companies, in an address before the Board of Trade of Chelsea, Mass., said that the "average increase per mile for street railroads in Massachusetts is $10,000 with the elevated trackage included. Street railroad companies in Massachusetts are at this time approaching a critical period. They made large investments when the cost of operation was much lower than it is now. Since the time of those investments the price of rails has advanced from $19 to $27, there has been an increase of 40 per cent. in the price of copper, an increase of from 25 to 30 per cent. in the cost of cars, an increase of 50 per cent. in the cost of motors, and other necessities for railroad operation have increased in proportion. I have seen the time when one cent was considered a good profit in street railroad operation, but now the stockholders are pleased to secure a profit of six mills."

◆

During the electrical show, which will open at Chicago January 15, there will be three conventions at the Coliseum—the Northwestern Electrical Association, the Electrical Salesmen's Association and the Credit Men's Association of the Electrical Trades.

◆

The statement that the Westinghouse Machine Company equipped the new Cunard steamship, the "Carmania," with Parsons turbines, is an error. The "Carmania's" turbines were built in England, and neither the American nor the British Westinghouse interests had any connection with their construction.

◆

Dr. Herault, of France, has started his electrical smelting experiments at the Consolidated Lake Superior Company's plant at the Soo. The experiments will probably occupy a year or more. So far as Canada is concerned the steel industry will be entirely revolutionized should Dr. Herault establish the commercial feasibility of his scheme.

◆

A Christmas greeting by wireless telegraphy was sent at midnight Sunday by Admiral Manney, chief of the Bureau of Equipment, Washington, to all the naval officers in command of navy yards along the Atlantic coast and to the wireless telegraph operators. The message was: "A Merry Christmas." Aside from the sentiment of the communication, which was sent from the Washington Navy Yard to the wireless stations from Maine to Porto Rico, Cuba and the Isthmus of Panama, Admiral Manney was anxious to get some idea as to how long it would take to relay the message, if necessary, and to determine how many stations would get the message. The answer from Admiral Rogers at Guantamo broke the record for wireless telegraph achievements in the navy, and perhaps in the world, considering that the transmission was over water and land, including the mountains of Cuba. The distance in a bee-line is 1,500 miles. The nearby stations, such as New York, Atlantic City, Hampton road, etc., were easily reached and the messages came back shortly after midnight.

THE NEUCHATEL ELECTRIC TRAMWAYS.

BY C. SMITH.

The picturesque city of Neuchatel, Switzerland, with its population of nearly 36,000, has recently had an electric tramway installed, the horse car system heretofore in service being abandoned in its favor.

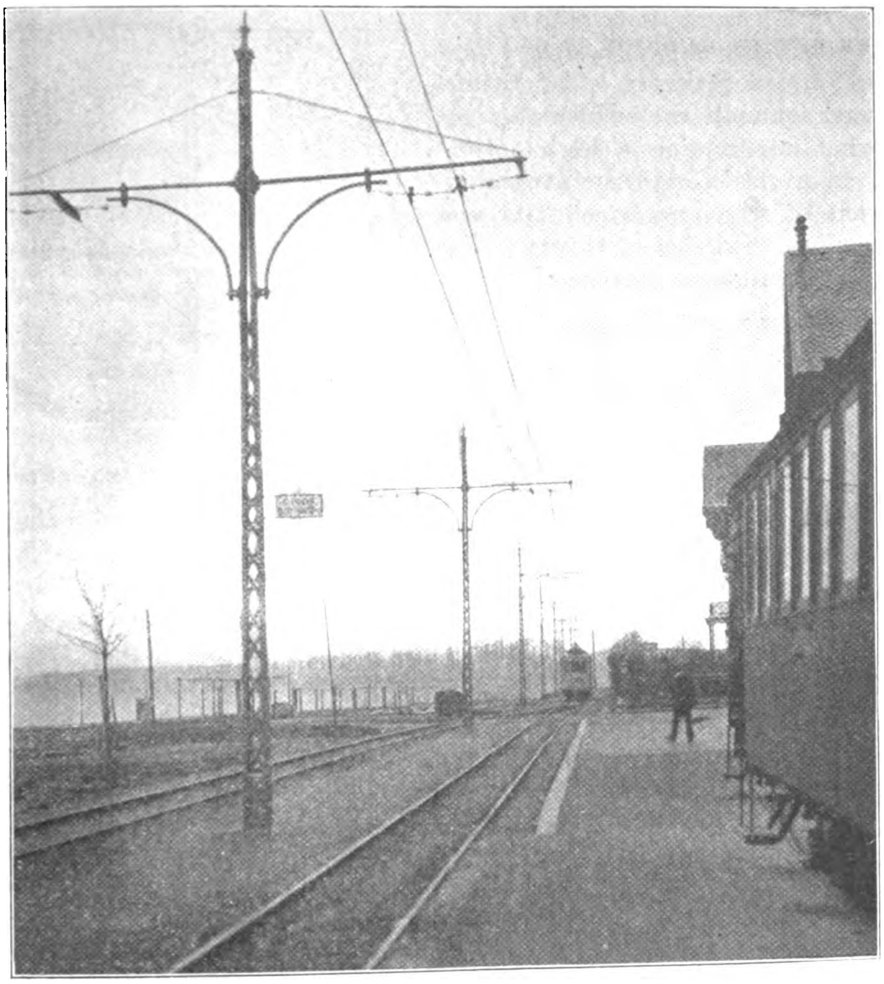

Fig. 1.—Neuchatel-Cortaillod-Boudry Line.

In 1900 the Compagnie des Tramways de Neuchatel, controlling the lines within the city, consolidated with the company owning the interurban lines, principally the Neuchatel-Cortaillod-Boudry section, so that the combined interests now operate all the numerous electric railways centering about Neuchatel. Various sections of the road were successively electrified and put into operation, the entire work having been recently completed by the Maschinenfabrik Oerlikon of Oerlikon, near Zurich, Switzerland, who were placed in entire charge of the electrical equipment and installation of this road by the Compagnie des Tramways de Neuchatel.

The direct current used is generated at a central station located in the city and is supplied to the overhead conductors at a tension of 580 volts. The interurban lines to Cortaillod and Boudry receive their current from either this power house or from the hydro-electric station of Clees.

The interurban lines centering about Neuchatel are very numerous, there being in all five separate divisions. The first section extends to St. Blaise and Serrieres and consists of 7,534 kilometers of single track and 740 meters of double track. The second line leads to the villages of Corcelles and Cormondreche, while the other three divisions extend from Neuchatel to Vauseyon and Valangin, Bahnhof, Boudry and Cortaillod respectively, the total length of track of the six lines being 26,309 kms.

The grades on all these divisions are very steep, grades of 40 per cent. and higher being met with. The gauge is ordinarily one meter, but the track construction of the various sections varies greatly owing to the fact that they were constructed at different times. The rails are of both the Vignole and Demerbe types and weigh from 20 to 33 kilograms per meter.

The tension on the line is, as before stated, 580 volts and the maximum fall of potential is 5 per cent. With the exception of the Boudry and Cortaillod section, all the overhead conductors consist of copper wire, 9 mms. in diameter placed 6 meters above the ground. Within the city iron poles are used while outside the limits wooden ones support the lines by means of the usual cross wires and rosettes used in such cases.

On the Cortaillod section the overhead conductors are octagonal wires of 100 square mm. section, and the three wire system is used, two of the conductors being overhead and the rails forming the third, there being a tension of 580 to 600 volts between the rails and either of the aerial wires, and 1,160 to 1,200 volts between the overhead conductors. In the other divisions there is but one overhead wire. Fig. 1 is a view on the Neuchatel-Cortaillod-Boudry line. It shows the overhead construction plainly, while Fig. 2 shows the tramway line entering the village of Valangin. Lightning arresters are used to protect the lines from atmospheric discharges.

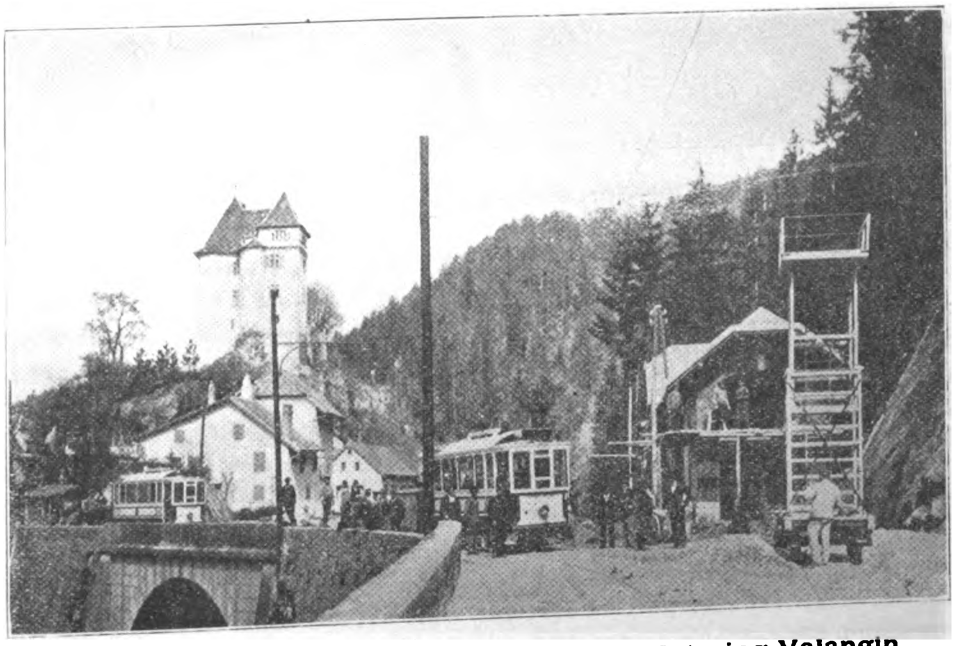

Fig. 2.—Neuchatel-Vauseyon-Valangin Line Entering Valangin.

There are in all 30 motor cars and 10 trailers in service at present, and of these

7 motor cars and 4 trailers are used on the Cortaillod-Boudry section. Three postal cars, several ballast cars and a snow-plow complete the rolling stock of this road. The cars on the majority of the lines are 8.5 meters in length, buffers included, and contain seats for 18 passengers with standing room for 16 more. Both electric and pneumatic brakes are used on these cars, which were supplied by the Compagnie d'Industrie Suisse of Neuhausen, while the Fabrique Suisse de Wagons of Schlieren furnished the larger cars for the Boudry section.

The majority of the cars have two Oerlikon motors of 18 hp. capacity, but which can develop a maximum power of 25 hp., with reduction gearing of 1 : 4.5. The lighting and heating is accomplished by electricity, six lamps being used, connected in series.

The larger cars on the Cortaillod-Boudry division are equipped with 40 hp. Oerlikon motors, which have a speed of 635 revolutions per minute, the reduction gearing being 1 : 4 in this case. The cars are lighted by 13 electric lamps, while two electric heaters, with a current consumption of 2,000 watts, are utilized for heating purposes. Fig. 3 is a view of the line near Peseux.

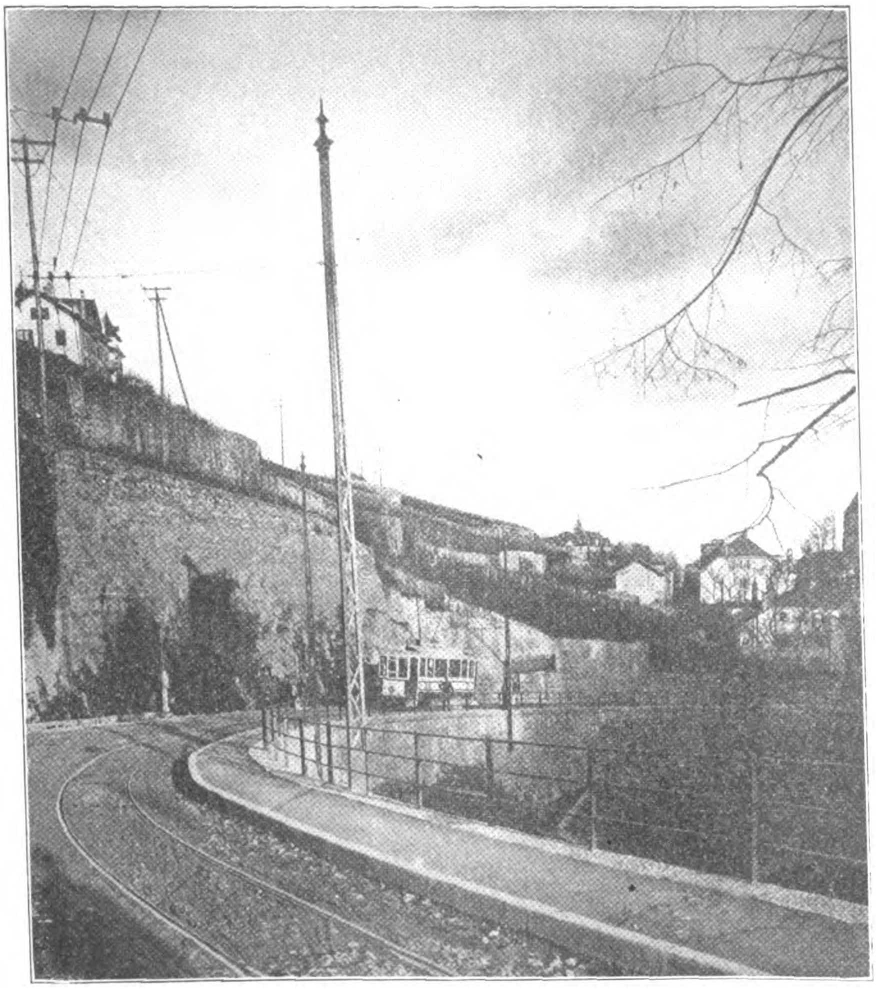

Fig. 3.—Neuchatel-Corcelles-Cormondreche Line Near Peseux.

The speeds on the different sections vary greatly, running all the way from 10 to 22 kilometers per hour. The speed attained on the Cortaillod division is still higher, reaching 30 kilometers per hour.

* * *

LIGHT, HEAT AND POWER PRINCIPLES.—XIV.

BY NEWTON HARRISON, E. E.

High Tension Switches.—To obviate the danger found in the sudden opening of a switch interrupting a high tension circuit an invention has been introduced by means of which such circuits are broken in oil. Switches of this type are called high tension oil switches. They are generally introduced in the main circuits leading from high tension alternators. The fact that a circuit may be made and broken under oil, has added greatly to the safety of installations requiring such protection. The commercial pressures now employed range from 2,000 to more than 60,000 volts, depending upon the nature of the plant. The safe handling of such pressures is best secured by automatic means, as it is evident that personal risks are exceedingly high, not so much because of the lack of insulation or other provision against danger, as much as the possibility of the presence of a temporary fault, giving rise to possible fatality. One large manufacturing concern makes switches operated by means of a spring and a motor. It is called the machine type oil switch, and consists of a powerful spring, which acts as the operating force in opening and closing the switch. This spring, however, is coiled by means of a motor of small size. Every time the switch is opened or closed, the motor operates automatically to an extent which is necessary to preserve the normal conditions. By this means, the station attendant is free from risks inevitably present, due to the personal handling, which would be otherwise obligatory. Long tubes are employed, to which each wire of the high tension circuit is attached; and further protection against flashing is afforded by means of a concrete partition separating the high potentials of the said wires. Flashing is one of the accompaniments of high tension circuits when made and broken under conditions which are not correct, such as defective insulation, bad contacts, or temporary defects in the switch, or in its design and construction.

High tension cable

Principle of the method of securing a high tension break in oil.

Sparking Distances.—It is important to note the sparking distances due to different pressures in connection with high tension circuits. These distances naturally vary with external conditions, such as air pressure, moisture, etc. They are also increased in high tension circuits by the development of peculiar conditions, which momentarily raise the pressure far above its normal value. According to the figures given, the potential necessary to jump 1 inch in air is 30,000 volts, but it is also evident, that if through any cause, such as mentioned, the spark does jump across, then the arc forming will reach far more than a distance of 1 inch with a 30,000 volt pressure.

Requirements of Switches.—The requirements of switches for high and low pressure service, may be enumerated for reference in the following list of items:

SWITCH REQUIREMENTS.

1—Switches must break a pressure of from 2,000 to 60,000 volts.

2—Switches must be safe and sure in operation.

3—Switches must not burn contacts under any circumstances.

4—Switches must have perfect contact between parts that touch.

5—Switches must have a high efficiency, wasting little or no power.

6—Switches must have low heating, secured by ample cross-sections.

7—Switches must have interchangeable parts, thus securing a ready means of continuing the service in case of injury at this point.

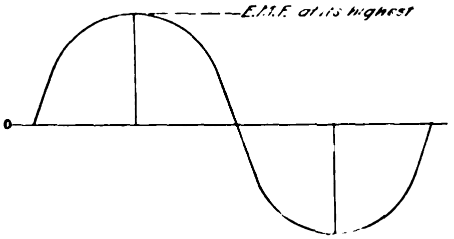
8—Switches must be constructed of non-combustible material, and thus lower fire risks to a minimum in connection with them.

9—Switch parts must be capable of ready inspection for the ready discovery of faults in case they are developing under severe service.

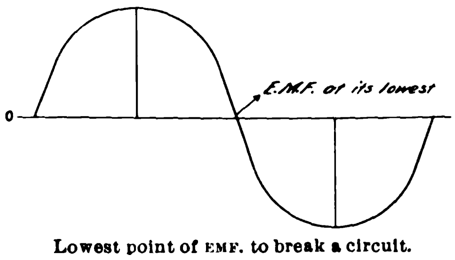
10—No exposed metal parts, thus removing the likelihood of, and freedom from, accidental contact with conductors of any description.

11—Safety to attendants, through the systematic inspection of the switches and their design, and to cover the above features of construction.

Point of Breaking the Circuit.—The breaking of a circuit carrying an alternating current is accomplished in one of two ways: either to break the circuit when the EMF. has attained the very peak of its wave, or when it has reached the lowest point of its wave. At the highest point or peak, the pressure being at its maximum, the arcing tendency is also at its greatest. According to the manufacturers of high tension switches, to quote: "The tendency to arc is much greater with a lagging current where the peaks of the wave of EMF. and current are not coincident in time, if the circuit is broken when the highest point of the EMF. is reached. The point of breaking the circuit, if of high tension alternating, is therefore that point at which conditions are most propitious—the point, in other words, at which a low pressure, or zero is found in the alternating wave."

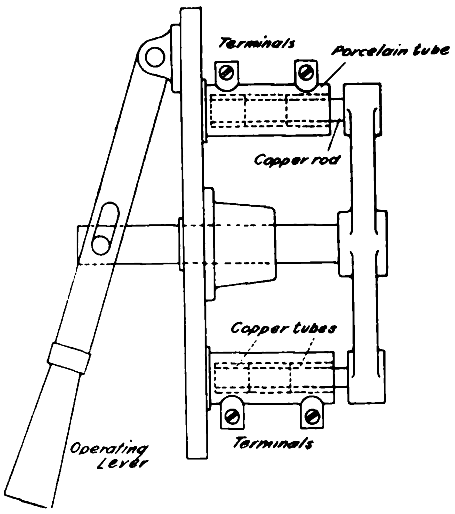


High pressure point of breaking a circuit.



Lowest point of EMF. to break a circuit.

Switches for 1,100 and 2,200 volts.—The so-called plunger type of switches were designed with the express purpose of eliminating arcing as far as possible. The principles upon which their construction is based may be covered by the following series of statements in this respect. First, the fact that arcs cannot be maintained after a circuit has been broken quickly and effectively; second, that the primary tendency of an arc is to expand until it has attained dimensions which the EMF. and resistance, according to Ohm's law, naturally demand. Third, that an arc cannot be readily maintained in a confined space; fourth, that an arc will not resist a strong transverse current of air. These features are combined in this type of apparatus and developed to meet the particular class of machines for which they were designed. The use of porcelain cylinders horizontally situated, and a marble slab upon one side of which the handle is mounted for the operators' use, and on the other side the mechanism which can be best described as given by the manufacturer's bulletin as follows: "No charged metal parts are exposed on the operating side of the base. A cast iron frame is mounted upon the back of the marble base, and serves as a support for the porcelain cylinders and as a guide for the operating rod which passes through the frame and is controlled by a handle in front. The long handle furnishes a powerful leverage and gives ease and certainty of operation. The handle being on one side of the marble slab and the switch terminals on the other side insures absolute safety to the attendant. One switch terminal is mounted at each end of a porcelain cylinder. Each cylinder has a half inch bore, through which a copper rod or plunger passes making the electrical contact between terminals. The losses in consequence of these contacts are kept very low, contact being made on all sides of the cylindrical plunger, which prevents heating and maintains a high efficiency of the switch. The plungers are self-aligning, and are entirely insulated from the iron cross head. The only charged metal on the switch consists of the plungers and the two terminals on



Mechanical operation of plunger switches.

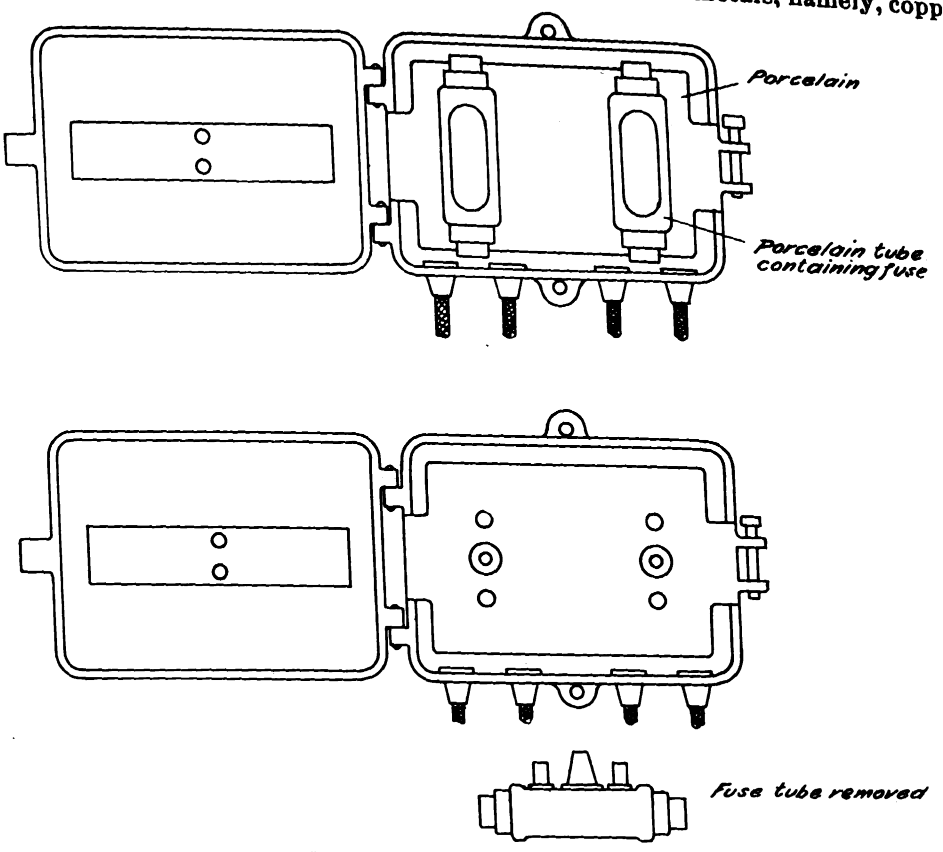
each porcelain cylinder. The cross head, operating rod and handle are completely insulated from all live metal. In opening the switch the plunger is withdrawn from the lower contact, and the arc which tends to follow it is destroyed by the combined effect of the cooling action of the porcelain walls and the draft caused by the expansion of the heated air through the outlet from the porcelain tube.

Those having one porcelain cylinder in each leg of the circuit, giving two breaks in series, are known as "single break." Switches having two porcelain cylinders in each leg, giving four breaks in series, are designated double break switches. The breaking capacity of a switch being directly affected by the character of the load, or power factor, different ratings are necessary for non-inductive loads and for loads having more or less lagging current. Current furnished to incandescent lights supplied from transformers fairly loaded has little or no lag, and is therefore practically a non-inductive load. Current to operate motors, arc lights or very lightly loaded transformers has a certain lag, the power factor being something less than 100. The power factor of 75 assumed in the table is a safe valuation for a circuit supplying general power service on many unloaded transformers. An increase in the frequency causes increased tendency to arc and consequently decreases the current breaking capacity of any given switch."

BREAKING CAPACITY OF PLUNGER SWITCHES.

Character of load,	Lighting or non-inductive load.				Power load with a power factor of not less than 75 per cent.			
Alternations	7,200		16,000		7,200		16,000	
Voltage	1,100	2,200	1,100	2,200	1,100		2,200	
Breaking capacity in amperes for single break	100	50	100	50	60	25	25	
Breaking capacity in amperes for double break	200	100	200	100	150	75	50	30

The principle followed out in switch design, is one from which the best lesson can be taught as far as construction is concerned. It is the fact, that the number of breaks in the circuit will to a certain extent determine the amperage that can be arrested. For instance in the table given of such items the breaking capacity of a single and double break switch of the same number of cycles per second is as 2 is to 1. The rating of the switches differs, but their carrying capacities are all 200 amperes. The rating is therefore determined by the breaks in the circuit and not as might be supposed, by the actual capacity of the switch.



Fuse boxes with removable tube fuses.

Transformer Fuse Blocks.—The protection of the primary circuit against overflows of current is best secured by means of fuses attached to specially constructed fuse blocks. Fuse blocks are constructed so that they may be readily applied to service at any convenient point on or near the transformer. The fuse wire itself is made of an alloy of lead and antimony or other metal, which fuses at a fixed temperature with a given current. It is protected from injury by being inserted in a porcelain tube, as well as acting to protect the lineman's hands from injury in case it volatilizes while being inserted. It is recommended that lead wire be used for currents of 10 amperes or less, and for higher currents, copper or aluminum. The sizes relating to these latter two metals, namely, copper and aluminum, are given as follows:

GAUGE SIZES AND CURRENTS OF COPPER AND ALUMINUM FUSE WIRES.

Current in amperes.	Size of wire in B & S gauge for copper.	Size of wire in B & S gauge for aluminum.
10 to 15	No. 24 B & S	NO. 23 B & S
15 to 20	No. 23 B & S	No. 22 B & S
20 to 25	No. 22 B & S	No. 21 B & S
25 to 30	No. 21 B & S	No. 20 B & S

Single and Double Pole Fuse Boxes.—For pressures of from 1,000 to 3,000 volts the regular single pole fuse block is limited by its construction to the use of fuses of the character designated above. The double pole fuse block employed for similar voltages is generally found in service with transformers not exceeding 10 kw. capacity of 1,000 volts pressure; and for transformers not exceeding 4 kw. capacity of about 3,000 volts pressure. The amperes vary in all cases, as far as these capacities are concerned, from 10 to 30. The unique features of construction are found in the use of porcelain tubes containing the fuses. These are air-tight, with the exception of a small opening at the back to allow gases to escape. Arcing is rendered impossible by the very nature of the space in which it occurs, the arc extinguishing itself automatically. The tubes are held in place by strong spring clips, which also serve as a switch, because when the tubes are lifted out only the primary of the transformer is entirely disconnected. Through the use of this principle the tubes can be lifted out and loaded with new fuses without unusual risk to the lineman. On the other hand, the blowing of the fuses means a sudden expansion within the tube, the effect of which is to destroy any arc about to form. Lateral expansion in this case is an absolutely reliable means of destroying arcs naturally tending to form with high pressure circuits.

PRIME MOVERS FOR GENERATORS.

BY W. H. WAKEMAN.

ARTICLE I.

Timid and superficial students, or readers of the mechanical papers, sometimes ask if the electric motor will entirely supersede the steam engine, but there is no more danger of it than of the passenger car superseding the locomotive, for the simple reason that the electric motor is not a prime mover. How, then, can it displace a prime mover in a broad sense of the word?

When a party who has been using a small steam engine in his business concludes to dispose of it and install an electric motor in its place it always leads somebody to conclude that the steam engine is doomed. They seldom stop to consider that the power this man continues to use is still produced by means of the steam engine, although said engine is in a big power house down town and the power comes up over a wire or two, therefore just as much steam power is used in that place as ever before.

It is not always necessary to use a steam engine for this purpose, however, as other prime movers are available for this purpose, and to call attention to these is the object of this article.

There are scores of towns and small cities that are within reasonable distance of a stream of water flowing down from a mountain that is capable of developing power enough to run several shops during the day and light the place at night. This could be utilized to run a generator producing current at a high voltage that can be transmitted a few miles with small loss of energy.

A motor can be installed at some suitable place and run by this current. Two generators may be located on the same shaft, one for a constant potential direct current of 220 volts to a three wire distributing system, supplying incandescent lamps at 110 volts potential, and motors of either 110 or 220 volts to good advantage. The other generator can be used to supply a constant current system of street illumination that gives satisfactory results.

Fig. 1 shows this motor and the generators or dynamos mentioned, with a clutch on either side of the motor, so that either generator may be stopped at pleasure.

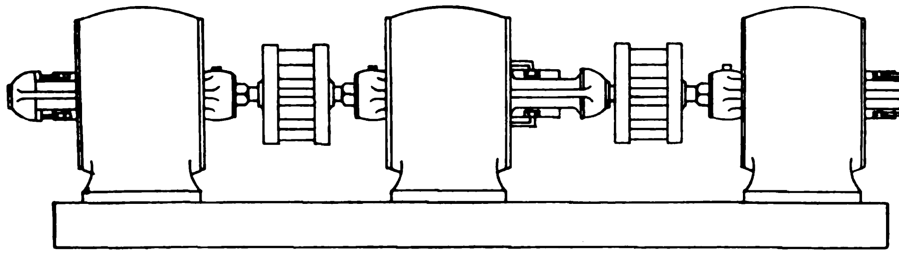


FIG. 1.

It may be well to state in this connection that with a constant potential system, the voltage does not change when lights are turned on or off, as more or less current or amperage is supplied to meet the changing demand.

Where a constant current system is used the amperage does not change, but is usually maintained at about 10 amperes. As more or less light is wanted the potential or voltage is changed to meet different requirements.

The greatest rival of the steam engine at the present time is the gas or gasoline engine. Fig. 2 illustrates a gas engine direct connected to a slow speed dynamo. This popular form of prime mover would be used even more than it is were it not for some of the objections to it.

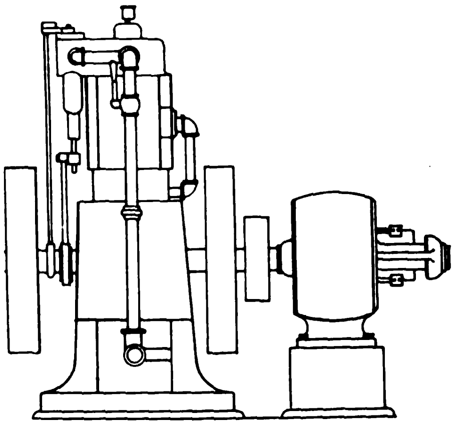

FIG. 2.

While this machine does not require a boiler, still a gas engine alone frequently costs as much as a steam engine and boiler together, which eliminates the advantage mentioned, so far as first cost is concerned, and that is a very important consideration in a majority of cases.

The reason for this great first cost is partly due to the fact that for the same power a gas engine must be much larger than a steam engine. The latter develops power at every stroke, while the former gets an impulse and develops power at every other stroke, if it is of the two cycle type, or once in four strokes for the four cycle kind. This makes it necessary to provide two heavy balance wheels on the engine, and sometimes one is put on the dynamo. These are not fly-wheels (although they are sometimes called by this name), for that signifies a wheel that carries the main belt on an engine.

A gas or gasoline engine may be used to charge a storage battery that will supply lights that burn steadily, but this method is too costly and cumbersome for general use on a large scale. This prime mover must be started by some external means, and this is an objection to the smaller sizes, as they are usually started by turning a crank which is sometimes dangerous and always disagreeable. Where the plant is large enough to warrant it devices for compressing and storing air are installed. The gas engine is then started by compressed air in almost the same way that a steam engine is started, and when full speed is attained the air is shut off and gasoline admitted.

If an engine of this type is overloaded it will stop instead of slacking up and continuing to run at a lower speed. If this takes place with a load ef electric lights, making it necessary to restart the whole plant, it causes much trouble and annoyance which cannot be tolerated.

In the vicinity of my desk there is a large plant for making producer gas that is used in gas engines that are direct connected to generators. These supply current to run motors in many parts of a large shop, proving economical in the use of fuel and satisfactory on general principles.

The manufacture of producer gas is a very simple process. It consists of putting a layer of coal several feet thick into a hopper prepared for the purpose. The lower part of this coal is kept burning brightly by a mixture of steam and air forced upward through it, resulting in gas composed of carbonic monoxide, hydrogen and nitrogen.

The latter is not wanted as it is of no value whatever, but it seems to be inseparable from the use of air that is required to burn the coal. When this gas is burned directly in the cylinder of an engine it completes an economical process.

Steam can be produced in a boiler under practical every day conditions with but little loss of heat contained in the coal. This is mentioned here because it is frequently misunderstood, and the steam plant unjustly condemned. The unavoidable loss is due almost entirely to the fact that a greater portion of the heat is lost in the exhaust steam, as no means of utilizing it in the production of power, have yet been discovered.

THE YOUNG IDEA.*

Scene.—Engineer's office at power station.

Time.—Office hours, any day, all the year round.

Curtain lifts and discloses engineer surrounded by papers, drawings, files and baskets, deeply engrossed in manipulation of inevitable slide-rule.

Enter, after knocking, portly dame in red hat, trimmed to overflowing with green feathers, and wearing complete week-end costume.

She advances against the engineer, smiling fearfully, draws a chair to her, sits down in a strategic enfilading position, and opens fire thus:

P. D.—I think you look after the electricity engines, don't you? This electricity is such a wonderful thing, isn't it? It always puzzles me, you know, but I should like to find out all about it. My husband's brother's brother-in-law does a bit at it in his spare time; you know him, I daresay—Tom Jones, lives just a few doors down our road; I'm Mrs. Hawkins, 101 Bell Street—put that down so's you don't forget it. As I was saying, he's a clever chap, Mr. Jones is, knows all about the bells, and puts our electricity to rights when he comes round to have a bit of tripe with us—won't you come one evening to meet him, he'd be very pleased, I'm sure? No formalness about him, you know. Well, as I was just going to say, when you put it out of my head, this young feller used to try to explain all about the electricity and magneticizm to me and Hezekiah—that's my husband, you'll like Hez.—but I couldn't keep up to him, and I says: "You're too clever for me, Tom, I says, but you give it to Henry"—that's my boy, he's 14 come Michaelmas—"you give it all to him, and praps he'll make an electricianer one day. So Tom tells the dear lad all about the positives and negaltives, and how he's never to touch anything painted red, because its sure to be magneticized and might kill him dead, and he shows him what he calls experiments with rulers and sealing wax picking up things; so that Henry knows nearly as much about it as Tom, and is forever cutting the bell-wires and joining them up again, and stopping the bells ringing, until I wish he wasn't so clever. Well, what I came here for was to ask you whether you can find him something to do about your engines. He wouldn't want much to begin with, because he might have to be taught a few little things—place might be a bit strange like—but you'd find him a clever lad. Now, what do you think about it?

Engineer.—Madam, at the present moment I am incapable of thought. If you would be good enough to leave your address—oh! yes, I have it here—I will communicate with you later. Good morning m'a'm.

P. D. (rising).—Thank you very much. I forgot to show you his photo. Here it is, but I always say it isn't very flattering. (Hands cabinet photograph of sickly looking youth dressed in a black suit that looks as if it had been cast on him, standing straight up with heels together, one hand stiff at his side and the other resting—planted would be a better term—on a couple of large books, which lie on a wool-work mat at the edge of an oval table with one central leg.) Praps you would like to keep it by you for a day or two. I'm sorry you can't give me an answer now, but I'll call round again in a day or two. It's no trouble at all, thank you, because I often have to be passing. Good morning sir. I am glad to see you looking so well. Any evening you like to call we shall be glad to make you welcome. Good morning. I wish I had time to stop and find out something about this electricity. Such a wonderful thing, I always say, and (looks at engineer admiringly) I suppose you know all about it. Well, good morning, I hope I have not interrupted your business at all, but I expect you are glad to see people sometimes, it must be so lonely up here all by yourself. What a funny card! What does it say. "For every minute I am delayed I have to work overtime!" Well, I never! You don't mean to say they're that hard on you? I wouldn't have Henry treated like that! What a shame! Well, of course, they can't say I've delayed you, because I came on business. Good morning (leaves).

Engineer.—Good morning, madam. (Presses one of a row of buttons on his desk. Presently enter boy.)

Engineer.—If you ever show that woman up here again you young scoundrel I'll break your silly little head!

(*Curtain falls on boy expostulating, and then dodging something heavy.*)

SOME CONSIDERATIONS DETERMINING THE LOCATION OF ELECTRIC RAILWAY SUB-STATIONS.*

BY C. W. RICKER.

No attempt will be made in this paper to define the conditions under which indirect distribution, through the medium of transformer sub-stations, is more economical than direct distribution from one or more generating stations containing prime movers. It is assumed that because of the size of the railways to be considered, and the local conditions determining the cost of generating power, the indirect method of distribution has been selected as offering the best economy in commercial operation, and an attempt will be made to outline a general method for determining the number and location of sub-stations.

In many cases, perhaps the majority of cases, a general solution of this problem is quite impossible. Most of the large electric railway systems now in existence are the result of development not foreseen by their original projectors, and there is little reason to believe that future systems will be very widely different in this respect, but probably they will continue to grow by extensions and consolidations depending upon the distribution and development of local centers of industry and population.

For convenience of discussion, electric railways large enough to require indirect distribution may be classified as follows:

1. Large simple networks, serving a single community.
2. Long single lines or groups of such lines, connecting separate communities or different parts of a very large one.
3. Complex networks, with connecting lines, serving a city and its suburbs.
4. Several networks with long connecting lines, serving separated communities.

Railways of the last named class are usually consolidations of the local systems of neighboring cities or towns, and interurban lines which frequently furnish power for lighting and general use in the towns served. There are usually well-marked centers of load which, together with local business conditions, determine the position and equipment of sub-stations.

---

* Communicated to the "Electrical Review," London.

* Paper presented at the 202d meeting of the American Institute of Electrical Engineers, New York, December 15, 1905.

Railways of class 3, those serving a large city and its suburbs, are also most often the result of the consolidation of separate lines and networks, and while the large central network belongs in class 1 the outlying districts present a difficult problem to the engineer, for he must anticipate the direction, character, and sequence of growth so as to provide against it. This requires an intimate knowledge of local conditions, both industrial and social, and in addition he has need to be something of a prophet to foresee the changes which the building of new lines and the starting up of new works may produce. The problem is a local and particular one, and must depend mainly upon individual judgment for its solution.

Classes 1 and 2 can be treated more generally. Take first the case in which a large network, or long line or group of lines, is contained wholly within a large city, so that a fairly uniform schedule can be operated over the whole, and the mean load upon each mile of road is approximately uniform throughout the system, at any given time. It is required to adjust the cost of losses in the primary distribution, the secondary distribution, including the track, and the sub-stations, the fixed charges upon each of these three divisions, and the cost of sub-station attendance, so that their sum shall be a minimum, with due regard to the conditions of regulation and continuity of service.

As the density of the load in such a system is very great, the unit of sub-station equipment may be made large enough, so that at the time of least load, one unit per sub-station may be operated at or near its best efficiency. Hence the sub-station losses per kilowatt-hour may be considered constant.

The aggregate capacity of the sub-stations will equal the capacity of the generating station plus the sub-station reserve capacity, if any is necessary, which will not exceed one unit per sub-station. The greater the distance between sub-stations, the larger the sub-station unit will be; hence the cost of sub-station apparatus will decrease as the number of sub-stations increases, until the largest practicable unit is reached. The same is true of sub-station land and buildings.

The cost of sub-station attendance will depend only upon the number of sub-stations, as the same number of attendants is required in a small as in a large sub-station, unless the cost of land makes it necessary to double-deck the sub-stations, which will cause a sharp rise in the cost of attendance when the number of units becomes greater than can be placed on one floor.

When direct-current motors are used, the secondary voltage is fixed by conditions of standard practice. The secondary conductors may be proportioned by Kelvin's law, subject to the limiting condition that the lowest potential shall be enough to allow the required acceleration. As the number of sub-stations increases, the cost of the conductors will decrease rapidly. The energy losses in the conductors may be constant or decreasing. The primary distribution in this case must be by underground cables. The primary voltage will be determined by the relative cost of copper and insulation, and should be as high as is consistent with safety. Hence the losses per mean kilowatt in the primary distribution may be considered constant. The total weight of primary conductors will be practically independent of the number of sub-stations, depending upon the total energy and the mean distance of distribution, and may be determined by Kelvin's law.

To obtain the greatest reliability of service, each sub-station should be fed directly from the generating station by at least three cables, and in the case of a wide difference in the number of sub-stations considered, the total cost of cables and conduits would be somewhat greater with the larger number of sub-stations as more and smaller cables would be required. Otherwise the cost of the high-tension distribution, and the losses in it, may be considered constant.

Neglecting those quantities which are constant, the fixed charges on sub-station land, buildings and apparatus, and the cost of sub-station attendance increase as the number of sub-stations increases; the fixed charges on the secondary distributions decrease and the losses in the secondary distribution decrease or remain constant.

The various losses and charges upon which the solution of the problem depends may then be considered as constants or variables dependent directly upon the number of sub-stations and inversely upon the distance between sub-stations. These quantities may be reduced to a common base of annual kilowatt hours, and curves representing them may be drawn with respect to the number of sub-stations as one co-ordinate, and a summational curve may be drawn which, if the premises are rightly chosen, will indicate the number of sub-stations at which the sum of the various charges is a minimum.

In a far greater number of railways the load is not uniform throughout the system. This is true especially of the long interurban railways using a comparatively small number of heavy train units. The load at any given time is concentrated upon parts of the system, or travels from end to end of the long lines. In such a system, the aggregate capacity of the sub-station apparatus in operation at any given time is greater than that of the generators; hence the load-factor of the sub-stations is unfavorable, and in most cases the power-factor of the system is low.

In a solution by the method outlined in this paper, several new curves must be drawn in addition to those named. The first showing the all day losses in the sub-station apparatus, which will increase with the number of sub-stations. The second showing the losses in the primary transmission lines, which will also increase with the number of sub-stations, due to the greater length of lines and to the lower power-factor. The third showing the fixed charges on the primary transmission lines.

The last two curves are relatively much less important. It is possible by compounding or automatic adjustment of fields, to keep the power-factor of the synchronous converters very near unity, making the transmission losses more nearly constant, and independent of the number of sub-stations. In such systems it is not usual, and seldom practicable, to use separate feeders from the generating station to each sub-station; and the primary distribution is usually by overhead lines, generally supported on poles, which are used for other conductors as well. But with all the sub-stations along a single line of railway, or a group of such lines connected to one transmission line, the additional cost of extending the same for a greater number of sub-stations will usually be but a small part of the whole expense. So, for at least a preliminary consideration of the problem, the last two curves may be omitted and the same quantities used as are considered in the solution for a road having a uniform distribution of load, with the addition of one containing the all-day losses of the sub-station apparatus.

In systems consisting of long lines with infrequent train service, the cost of attendance and all-day losses in converter sub-stations often becomes so great that the regulation in secondary conductors economically proportioned for standard direct-current voltage will not permit the operation of the required schedule. The usual remedy is to set the sub-stations nearer together, though at the cost of operating economy.

If other conditions still make the use of standard direct-current equipment desirable, it would seem that better economy could be obtained by lengthening the sub-station sections and using boosters, just as has been found profitable in the supply of such lines of less length from direct-current generating stations. The fixed charges on and losses in the boosters should then be included in the curves of sub-station apparatus.

In the discussion of the method of treating the problem of sub-station location herein suggested, the usual type of converter sub-station, with direct current, secondary distribution has been kept in mind, but the method is no less applicable to a complete alternating-current system with static sub-stations, in which case the curves of sub-station losses, attendance and fixed charges, all become flatter, while the higher trolley voltage available, permits a wider spacing of sub-stations, without exceeding the limiting conditions of regulation, all of which indicate a better efficiency of sub-station apparatus and secondary distribution, in roads of low and non-uniform load density.

NOTES ON THE STANDARDIZATION OF FUSES.*

BY ALFRED SCHWARTZ.

The fuse in this country is considered by most engineers to be a tricky and unreliable piece of apparatus; it is often spoken of as if it were on the point of being superseded by the circuit-breaker—presumably in all sizes—and in general it is regarded by the up-to-date man as a legacy from the dark ages (i. e., the transition period between the gas age and the era of electricity), and further, he considers that while it has to be tolerated as a necessary nuisance, it is entirely unworthy of the care and attention that he lavishes upon other portions of his electrical equipment.

Whenever a fire takes place on premises in which the electric light has been installed, it is in the first instance invariably attributed by the lay press to "the fusion of the electric wires." In most cases, however, it is ultimately traced to the gas or heating arrangements, but it is none the less our business to insure the safety of the electric system by a well considered system of fuses, so arranged that their abuse shall be made as difficult as possible, and that their overload capacity shall be of a predetermined value.

Before considering in detail the various points in connection with fuses in which standardization appears to be desirable, we must clearly recognize that no amount of standardization will prevent willful and determined tampering with a fuse. Careful standardization will, however, reduce this danger to a minimum, by the selection of a form of terminal which will render its misuse as troublesome as possible; while at the same time the ability to obtain from any dealer's stock the standard fuse required would render the legitimate replacement of the fuse far easier than it is at present.

Let us now briefly consider seriatim the particulars in connection with which standardization could be advantageous:—

Length of Break.—The fire risk in connection with fuses should be greatly reduced, first, by standardizing the length of break not only for various circuit voltages, but also for various carrying capacities.

The sudden breaking of a heavy short-circuit current by a fuse produces an inductive pressure rise which may be very many times that of the line voltage. This is brought about by the collapse on breaking of the magnetic field due to the short-circuit current; this current if limited only by the resistance and self-induction of the circuit would reach a very high value—possibly from 5,000 to 10,000 amperes on an ordinary service fused for 50 amperes. If the circuit is properly fused, however, it will be opened before the current has had time to mount to the value named above, and the short-circuit current would in the case named be limited to about 1,000 amperes. The greater the capacity of the fuse the longer it will take to melt on short-circuit, and in consequence the pressure rise will reach a proportionately greater value. A standard increase in the length of break with increased carrying capacity should therefore greatly reduce the chances of the persistence of the arc and consequently the fire risk.

Short-Circuit Service.—The term short circuit is a relative one, and the effects which one may get on a consumer's premises connected to a large network are very much less severe than those obtainable on the station bus-bars. Some discrimination should therefore be used in standardizing, in order to avoid throwing on the general consumer the burden of the greater cost necessary for a fuse to withstand station conditions. Possibly two classes might be formed, one for fuses (usually of large carrying capacity) to withstand the severe conditions of a true short circuit, the other for fuses (usually of small carrying capacity) for use on circuits of a non-inductive character and of moderate resistance, such as one usually finds in connection with house installation work. As an alternative, some mean condition between these two might be specified in connection with the tests on short circuit with which the fuses would have to comply.

Material of Fuse.—It would appear desirable to specify the material, shape and arrangement of the fuse metal to meet the requirements of circuits which are capable of bearing different amounts of overload. For instance, an ordinary lighting circuit can usually safely withstand an overload of 100 per cent., and it is not desirable on such a circuit that the fuse should come into operation with a less excess current than that named; fuses arranged and rated to meet these conditions might be termed "insensitive" fuses. Arrangements might, however, be made for a further class or classes which would operate with excess currents of from 10 to 50 per cent., and which might be termed "sensitive fuses." Generally speaking, fuses of large carrying capacity would be placed in the latter class. Other points to be considered in connection with the choice of metals are:

1. The degree of purity obtainable commercially.
2. Resistance to oxidation at the temperature of normal working.
3. Freedom from the formation of an oxide skin of sufficient strength to hold up the metal when molten.
4. The non-arcing properties of the metal vapor.
5. The characteristics on disruption as to the formation of heavy vapors, the degree of scattering of the molten particles of metal, and their condition as to temperature, etc.
6. The contact difference of potential between the fuse metal and the terminals.
7. The coefficient of expansion of the fuse metal relative to that of the terminals or binding screws.
8. The form in which the metal is available whether in wire or strip, and its capability of being soldered satisfactorily.

Rating.—The normal fusing current for the materials sanctioned should be carefully determined for the requisite ranges, and the fuses stamped with the normal carrying capacity, and the fusing current and "sensitiveness" expressed as the percentage overload at which fusion takes place, the overload being reckoned as excess over the normal carrying capacity. The time should be specified within which the fuse must blow when started cold with the specified overload; this time will, of course, vary with the capacity of the fuse, and will be greater for inclosed fuses than for the open type.

---

*Abstract from the "Electrical Review," London.

Testing.—Arrangements should be made for standardizing the conditions and details of the following tests:

1. Normal fusing current.
2. Short circuits.
3. Arcing on fusion with currents slightly in excess of the normal fusing current.
4. Temperature rise for inclosed fuse covers.
5. Insulation between parts.

The normal fusing current for a wire may be defined as the minimum current required to fuse the wire in such a time interval as shall be necessary for the wire to have attained its maximum steady temperature. In order to obtain accurate results, sufficient time must be allowed for this to occur; for open type fuses a method of procedure can be detailed which will insure this, but for semi-inclosed and inclosed fuses the time interval necessary to bring them up to a given temperature will depend upon the special environment of the wire.

Contacts.—There are as a rule two sets of contacts to be considered:

1. The contact between the fuse wire or strip, and the end plate or ferrule of the holder or cartridge.
2. The contact between the end plates or ferrules of the holder and the clip jaws or terminals of the fuse block.

In some fuses of open type for fairly large currents, where the strip employed is of sufficient strength, it is forced edgeways between the spring terminal clips by means of an insulated grip handle, which can be removed when the fuse strip is in position, thus obviating one of the sets of contacts mentioned above. With regard to the contacts on the holders in the inclosed type, the fuse metal is usually soldered to the end caps, while in the open type it is usually held under a screw and washer. Where the fuse metal has approximately the same coefficient of expansion as the terminal, not much trouble is experienced, particularly with strip, but where the expansions are different, flattening of the wire may occur, and a loose contact will be developed. Where one of the metals is highly electro-positive to the other, local action will take place in damp situations, with consequent corrosion at the contacts. The form of contact between the fuse holder and the fuse block requires careful consideration; the knife blade and spring clip seems the most promising, as it is simple in construction and avoids the use of screwdrivers for replacement or disconnection, and it will, further, not become loose under working conditions. The only point against it is that it rather lends itself to abuse by the substitution of a strip of metal or wires in place of the fuse holder, but this could doubtless be overcome by a suitable arrangement of the block and terminals.

The spacing of the fuses should also be detailed, so as to secure a minimum distance between terminals of the same polarity, to allow of safe and easy handling. For fuses of the open type, incombustible septa of insulating material should be fixed between the fuses to limit the spread of the molten metal; the arrangement should also be such as to prevent accidental short circuit between live metal parts of opposite polarity. Open type fuses should preferably be arranged horizontally rather than vertically, as this is less likely to persist; the normal fusing current will, however, be increased by about 5 per cent.

◆

Meeting of the Independent Telephone Association of Wisconsin.

The Independent Telephone Association of Wisconsin held its convention at the Hotel Pfister, Milwaukee. December 21.

President Harper, in referring to companies who "made peace with the Bell," said: "I think that the traitors are about all in now and they have landed about all that they can land."

The secretary's report showed that Wisconsin has 300 independent telephone companies with an investment of $4,000,000; 1,300 toll stations, 375 exchanges and 42,000 subscribers.

The following officers were unanimously elected:

President—Richard Valentine, Janesville.

Vice-President—J. C. Kuoni, Sauk City.

Secretary and Treasurer—W. F. Goodrich, La Crosse.

◆

Proposals Invited.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting sealed proposals until January 9 for furnishing Eastern Navy Yards with the following electrical material: Schedule 294, arc lamp globes, wire, tape, fuses and miscellaneous supplies. Blank proposals can be obtained at the Navy Pay Office in New York or upon application to the Bureau at Washington.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DEC. 19, 1905.

Electric Railways and Appliances.

807,431. Electric Controlling Mechanism for Railway Appliances. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Leon F. Moss, same place. Filed June 3, 1905.

807,451. Car-Fender. Edward C. Haynes, Portland, Ore. Filed Aug. 23, 1905.

807,463. Self-Lubricating Trolley-Wheel. John Hensley, Huntington, Ind. Filed July 8, 1905.

807,477. Trolley. Allen P. Lord, Bradford, Pa. Filed Jan 9, 1905.

807,490. Car Fender. Frederick W. O'Connor, Toronto, Can. Filed May 8, 1905.

807,590. Railway Signal-Repeater. Frederick B. Wiegand and William V. Moak, Utica, and Francis B. Harrington, Menands, N. Y. Filed July 15, 1905.

807,653. Trolley for Electric Railway. Walter J. Barron, Brooklyn, N.Y. Filed June 6, 1900.

807.707-800. Electric Railway-Signal and Electric Railway Signaling Appliance. Henry A. Ammann and Albert D. Campbell, Spokane, Wash. Filed April 6, 1905.

807.895. Railway Signaling System. Henry Bezer, New Rochelle, N. Y. Filed May 25, 1895.

Electric Lights and Appliances.

807,671. Combined Socket and Plug for Incandescent Lamps. Henry W. Gremmels, Denver, Col., assignor of one-half to Martin J. Jackson, same place. Filed Jan. 3. 1905.

807,860. Electric-Hand-Lamp Contact. George L. Patterson, New York City, assignor to Alice C. Patterson, same place. Filed Dec. 30, 1904.

Electrical Machinery and Apparatus.

807,434. Casing and Terminal Block for Electrical Measuring Instruments. William M. Bradshaw, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed March 17, 1905.

807,517. Magnetic Work-Holder. Walter N. Vance, Chicago, Ill. Filed July 31, 1905.

807,520. Controller. Ferdinand Volk, Pittsburg, Pa. assignor, by direct and mesne assignments, of one-third to John A. Rogan and one-third to John Murphy, Pittsburg, Pa. Filed Feb. 4, 1905.

807,634. Circuit-Controlling Device. Gwynne E. Painter, Baltimore, Md. Filed July 18, 1903.

807,747. Insulating-Casing for Wire Connections. Louis A. Kling, Elizabeth, N J. Filed May 27, 1904.

807,847. Lightning-Arrester. Ernest S. Moorer, Anderson, S. C. Filed May 9, 1905.

807,858. Controller for Electric Motors. William A. Paris, Edgewood Park, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 3, 1905.

807,937-938-939. Electric Motor Controller, Control System for Electric Motors and Controller for Electric Motors. Henry D. James, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 3, 1905.

807,943. Regulating Means for Systems of Electrical Distribution. Benjamin G. Lamme and Charles F. Scott, Pittsburg, and Frank Conrad, Edgewood Park, Pa., assignors to the Westinghouse Electric & Manufacturing Company. Filed Feb. 1, 1905.

Telephones and Telephone Apparatus.

807,575. Means for Restoring Ring-off Drops for Switch-Boards. Ewing McLean, Greencastle, Ind. Filed Nov. 21, 1904.

807,596. Telephony. Edward A. Buell, Dekalb, Ill., assignor to the Selective Signal & Telephone Manufacturing Company, Sycamore, Ill. Filed Oct. 6, 1904.

807,806. Telephone. John H. Boyd, Valden, Miss. Filed Dec. 28, 1904.

807,859. Annunciator. James Patten and William Patten, New York City. Filed April 5, 1905.

807,942. Telephone-Directory. Edward N. Lake, Chicago, Ill. Filed Aug. 22, 1904.

Miscellaneous.

807,673. X-Ray Tube. Emil Gundelach, Gehlberg, Germany. Filed Dec. 16, 1904.

807,708. Electromagnet Recording Appliance. Henry A. Ammann and Albert D. Campbell, Spokane, Wash. Filed Feb. 17, 1905.

807,718. Thermostat. Peabody A. Brown, Denver, Col. Filed March 20, 1905.

807,870. Pole Changing Device. Harry O. Rugh, Chicago, Ill., assignor, by mesne assignments, to Edward C. Hennis, Sandwich, Ill. Filed June 2, 1902.

807,871. Electric Self-Playing Violin. Henry K. Sandell, Chicago, Ill., assignor to the Mills Novelty Company, Chicago, Ill. Filed March 27, 1905.

THE TELEPHONE WORLD.

No American Telephone Rights.

The stockholders of the American Telephone & Telegraph Company, at their special meeting last Thursday, approved by more than a two-thirds vote the resolution authorizing the directors to issue $150,000,000 convertible bonds from time to time as they may see fit. The total number of shares represented at the meeting was 1,438,136, of which 1,234,613 voted in favor of the proposition and 3,522 against it.

President Fish announced to the stockholders that the company as yet has no definite plans formulated for the proposed issue of $150,000,000 convertible bonds which was authorized, and made it clear that nothing in the way of "rights" would be likely to accrue to the stockholders as a result of the sale of the bonds, whenever such may take place.

President Fish in his remarks to the stockholders expressed the hope, as well as the belief, that the securities of the company, through the issue of these bonds, will find a wider market than they have met heretofore. "The condition of the company is to my mind satisfactory," he said, "and better than it ever has been before. One thing, however, which I do not like about our situation, and it is a matter of common gossip, is that we are a Boston concern. Boston and New England, much as I dislike to say it, are to-day in a way provincial, and not able to handle with entire satisfaction big enterprises which require large sums of money and a broad market for the securities. I am inclined to think that, if matters are carried out along the lines now planned, the securities of the American Telephone & Telegraph Company will find a market commensurate in breadth with the importance of the company, and its financial requirements. What its developments will be within the next 10 or 15 years, you may judge for yourself from what it has accomplished in the past."

The organization of the Citizens' Telephone Company of Caldwell, O., was lately consummated with the following incorporators: H. W. Kunz, V. K Herlan, J. A. Lemmax, Edward Spannagel, Charles H. Dew, L. W. Wheeler, J. H. Sparling, Florence Meek, E. S. Wilson, H. R. McClintock and William Simmins. The capital stock of $30,000 is held by the above named persons and the application for a charter was duly made. The board of directors has secured options on the property of the Farmers' Exchange Telephone Company of Caldwell and the Summerfield Telephone Company of Caldwell, and will take over those plants January 1, 1906. Just what the future development or business plans that this new company has in view were not made public, but it expects to fulfill the contracts of the respective companies at Summerfield and Caldwell.

The Independent telephone company is now in operation between Cooperstown and Oneonta, N. Y.

The Bath, Ky., Home Telephone Company capitalized at $15,000, has lately been organized.

The Rural Telephone Company of Edinburg, Pa., has been formed with $5,000 capital stock.

Independents Take Place of Bell Company.

A merger of the telephone exchanges of Tampa, Fla., has been announced whereby the Southern Bell Telephone Company abandons the local field, its plant, equipment, business and franchises being acquired by the Peninsula Telephone Company, the Independent company which has been operating in that city for several years.

The Ruston, La., city council has passed an ordinance granting permission for the use of the streets of that city for the construction of a new telephone service. A number of prominent citizens are behind the enterprise, and a canvass of the city shows that the merchants are unanimously in favor of organizing a home company. Enough stock to secure the new company has already been pledged.

The Black Springs, Ark., Telephone Company lately issued articles of incoporation. The capital stock is $5,000, of which $1,000 is subscribed. a ny is organized for the purpose of operating telephone lines in Montgomery and adjoining counties. J. A. Abernathy is president, W. C. Warren vice-president, C. C. Welsh, secretary, and W. C. Rowton, treasurer.

The Western Ohio Telegraph & Telephone Company, with headquarters at Toledo, O., and a capitalization of $100,000, was recently granted a charter by the Department of State. The incorporators are: John Meilink, A. C. Stevenson, F. E. Palmer, J. W. Davis and Joshua Lindall. The concern will do a general telephone and telegraph business with the termini of the lines at Toledo and Cincinnati.

At a recent meeting of the Thomson, Ga., city council, the local telephone system was leased from the stockholders with the privilege of buying the property later. The capital stock of the company will be increased and many needed changes will be inaugurated. The action of the council was in line with the views of the present administration, that all public utilities should be owned by the town.

The Independent telephone company of Fulton County, Gloversville, N. Y., has been formed to erect a telephone line. Its capital stock is $5,000 and incorporators: Frederick M. Young, Gloversville; William T. Briggs and Judson Baker, both of Johnstown, and others.

It is announced that the Automatic Electric Company of Chicago has recently received orders approximating 25,000 telephones. At the same time the business of the current year is quoted at $1,500,000. The automatic instruments have been installed in more than 75 towns and cities in the United States.

According to a report from Nashville, Tenn., the capitalization of the Cumberland Telephone & Telegraph Company is to be increased 20 per cent. January 2, 1906.

The Christion County Telephone Company of Taylorville, Ill., has increased its capital stock from $10,000 to $250,000.

Telephone Association to Meet in June.

James B. Hoge, president of the National Interstate Telephone Association, has given out the information that the next convention of the association would be held in St. Louis, Mo. Mr. Hoge thought that the convention would be held sometime in June, although the exact date has not been decided.

A new telephone company has been incorporated in Hammondsport, N. Y., known as the Pleasant Valley Telephone Company, with a capital stock of $5,000. This company combines nearly all of the rural lines entering the village. The stock will be taken by the 56 subscribers. The officers are: President, J. W. Brundage; vice-president, William Dildine; secretary, Pierre Brundage; treasurer. James H. Smelle. The lines are connected with the exchange there and with the Inter-Ocean at Bath and Penn Yan.

At the annual meeting of the Delaware Valley Telephone Company, held in North Sanford, N.Y., the following men were elected directors: J. W. Smith, E. E. Crane. C. A, Philley, U. D. Bailey, L. E. McCully, A. Colvin, D. D. Jones, Elmer Mills, Clark Henderson, C. B. Teed, C. W. Sampson, George Ireland and Floyd Gardiner.

Although the system of Independent telephone lines in Texas is composed of a large number of small units, the work of handling long distance business is very efficiently handled. All the companies work in perfect harmony, and a very satisfactory service is given.

The Eastern States Telephone & Telegraph Company of No. 15 Exchange Place, Jersey City, N. J., has been formed to construct electric telegraph, telephone and cable lines. Its capital stock is $1,000,000. The incorporators are: Henry A. Bingham, Cornelius A. Cale and Alex. F. Garbe.

The Reliance Telephone & Telegraph Company was lately incorporated in Jersey City, N. J., with a capital stock of $125,000. The incorporators are: Arthur Johns, Lanier McKee and Kenneth K. McLaren.

The Cameron, W. Va., Telephone Company has extended its lines to Garrison, Pa., where it connects with the Wadestown and Blackville lines, giving through connections with Morgantown and eastern points.

The Driftwood Telephone Company is to build a line from Capron to Alva, Okla. The company now has a line from Kiowa to Capron.

The Brooten, Minn., Telephone Company has been organized with a capital stock of $10,000. T. O. Shelso is president; A. A Mahlum, vice-president; and M. Reine, secretary.

The Diamond State Telephone Company is arranging to put in a party line for the farmers between Salisbury, Md., and Delmar, Del.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Bartlett, Tex.—The Bartlett Electric Light & Motor Company has been incorporated with a capital stock of $10,000 by R. S. Decker, R. G. Decker and W. R. Decker.

Batavia, Ia.—Ottumwa parties are interested in an electric light plant to be installed here.

Birdsboro, Pa.—An electric light plant is to be erected along the Schuylkill River in this city.

Brighton, Ala.—This town is to be lighted by electricity. Negotiations have been opened between the authorities here and the Birmingham Railway Light & Power Company.

Chicago, Ill.—Mayor Dunne has made public his intention of securing lower and more uniform electric light rates for the people of this city. He has directed City Electrician Carroll to gather data on the cost of maintaining incandescent lights. The mayor has already conferred with William G. Beale, general counsel for the Chicago Edison Company, and declares his belief that electric light rates are too high, besides being characterized by discriminations.

Cleveland, O.—Mr. Springhorn will ask the city council to appropriate money for the purchase of electric light globes, wires and poles, in order that the new city lighting plant can be run to its fullest capacity.

Creighton, Neb.—The citizens have organized a stock company, capitalized at $25,000, for installing an electric lighting plant.

Creston, Ia.—The Creston Mutual Electric Light, Heat & Power Company has been incorporated here.

Ellicottville, N. Y.—This town will soon have electric lights.

Fayetteville, Tenn.—B. E. and J. W. Holman, J. H. Thompson and T. W. Caudle, of this city, and W. J. Holman, of Huntingdon, have purchased the electric light plant at Dayton, Tenn., and a charter has been applied for. The capital stock of the company, which will be known as the Dayton Electric Light Company, will be $10,000. Improvements amounting to $2,500 will be made on the plant at once. J. W. Holman is president; B. E. Holman, secretary and treasurer; W. J. Holman, superintendent; T. W. Caudle, general manager.

Fremont, Neb.—The citizens are agitating the question of moving the electric light plant, which is soon to undergo improvements, including the installation of four new boilers, and it is believed the present is the proper time for the consideration of moving it.

Houston, Tex.—The Houston Electric Company has added $500,000 to its capital stock.

Killeen, Tex.—McDowell & Burks, of this place, have secured a 50-year franchise from the city to operate an electric light plant.

Marceline, Mo.—The Marceline Electric Light Company has been incorporated with a capital stock of $20,000 by George W. Early, William P. Callahan and Henry B. Early, to operate an electric light plant.

Ottawa, Ont.—The people of this city have invested $200,000 in a municipal electric lighting plant.

Pittsburg, Pa.—There has recently been organized in this city the Chemical Light, Heat & Power Company, a corporation chartered under the laws of the State of New York, with a capital stock at present of $500,000. This capital, however, is purely nominal, and in a short time will be increased to either $1,500,000 or $2,000,000. This company is chartered for the purpose of taking over and acting as a holding company for gas and electric light and power plants. The company was promoted by J. Francis Horton, who has been elected president of the company. The capital stock is about evenly divided between Pittsburg and Eastern capitalists.

Standish, Mich.—W. W. Vaughn has made application for a franchise to install an electric lighting plant in this city to succeed the one that has just expired.

St. Augustine, Fla.—It is generally believed now that this city will be supplied with electric lights within the next mouth or so.

Tarentum, Pa.—The directors of the Young Men's Christian Association have decided to put in an electric light plant.

Walkerton, Ind.—This place is to have electric lights. The question was decided at an election lately held here for that purpose. There were but seven votes against it, while 160 favorable ballots were cast.

STREET RAILWAYS.

Alliance, O.—It is stated by Stark electric officials that the Alliance-Cleveland electric line will be built, and that C. R. Morley of the Stark Electric Company will be one of the leading promoters.

Arkansas City, Kan.—The citizens of this place and Winfield are quite bent on having an electric railway built between the two cities.

Burlington, Vt,—Capitalists interested in electric railways will petition the Vermont Legislature for a charter for the Champlain Valley Electric Road Company. The route is through this city, Shelburne, Charlotte, Ferrisburg, Vergennes, Panton, Addison, Bridport, Shoreham and Orwell, with an ultimate outlet at Rutland. This road will be in competition with the Rutland Railroad and will do freight as well as passenger business.

Cincinnati, O.—The long-expected merger of the great trolley roads of Indiana and Ohio is to be accomplished shortly. Recent information from Indianapolis states that the Cincinnati, Dayton & Toledo, the Tucker-Anthony lines, the Columbus, Buckeye Lake & Newark, the Columbus, Cincinnati & Newark, and the Dayton, Springfield & Urbana will be the Ohio lines involved. The deal involves millions. The money is supplied by the Randall-Morgan and Widener-Elkins interests.

Corning, N. Y.—The Erie Railroad Company has decided to adopt electricity on portions of its system, also maintaining the present steam equipment. A third track will be built between this city and Binghamton, with cut-outs, which will be run with the modern electric equipment. Eventually, probably a large part of the Erie's system will be adapted to electricity, and this first section is meant as a trial.

Georgetown, British Guiana.—The Demerara Electric Company, operating the electric traction system of this city, has decided to overhaul its power plant, rolling stock and roadbed during the next six months in order to put everything in first-class shape. The interests that own the Trinidad Electric Company have acquired control of the Demerara Electric Company, and F. W. Teele has been appointed manager and consulting engineer to carry out the improvements.

Guthrie, Okla.—The Logan County board of commissioners lately granted a franchise to Thomas A. Smith to construct an electric line northward from this city, and to be known as the Newkirk, Tonkawa & Southern Electric Railway. The company must deposit a bond for $1,000 before the franchise is effective. The proposed line will run through Logan, Noble and Kay Counties, and is intended to connect here with the Guthrie-Oklahoma City Interurban, and at Chilocco with the Gueda Springs electric line.

Hutchinson, Kan.—Emerson Carey and Charles Williams, representing a score or more of local capitalists, have purchased the Hutchinson Street Railway Company and will change the present horse car line into an electric line. A company is being formed to finance the road.

Lamonte, Mich.—This city is soon to have a new electric road.

Lansing, Mich.—The syndicate composed of James R. Elliott, of this city, and Myron W. Mills and George T. Moore, of Port Huron, has acquired a controlling interest in the Battle Creek Kalamazoo Interurban Trolley Line, as well as in the lines in Battle Creek and Kalamazoo City. The lines now connected by a number of projected extensions are to be reorganized as the Michigan United Railways Company. Lansing will be the center of the new system.

Omaha, Neb.—Right-of-way for an electric road has finally been secured from Albright to Bellevue by the Omaha & Council Bluffs Street Railway Company. Contractors are already figuring upon the grading, and bids to do that work are expected to be in shortly.

Parkersburg, W. Va.—A charter has been applied for by the Middlebourne & Ohio River Railway Company for the purpose of constructing an electric line from Sistersville to Middlebourne. The company is composed of local people and John Shrader of Chester.

POWER PLANTS.

Grand Detour, Ill.—Another big dam is to be built across Rock River just above here by the Sandusky Cement Company for the purpose of securing electric power for its cement mills east of Dixon.

Lewistown, Ill.—The Fisher Power, Heat & Electric Lighting Company of this city has been incorporated with a capital stock of $20,000, by Floyd M. Condit, Theodore Fisher and H. W. Masters.

Prosser, Wash.—The county commissioners have granted a franchise to the Prosser Falls Land & Power Company to erect a power line along the county road to the western boundary. It is for the purpose of transmitting electric power to Sunnyside for lighting that city, and also to furnish its power, with which to pump water for the town.

Spokane, Wash.—The Washington Power Company of this city has secured a franchise permitting it to introduce electric power for any purpose into any part of Whitman County.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 18½@18⅝c. Lake 18⅝@18⅞c.; casting, 18@18½c.

New York Metropolitan Street Railway's regular quarterly dividend of 1¾ per cent. will be paid on stock January 16.

The General Electric Company has applied to the New York Stock Exchange to list $6,034,100 additional capital stock.

The Westinghouse Electric quarterly dividend of 2½ per cent. on the preferred assenting and non-assenting stocks is payable January 10.

The gross earnings of the Cleveland Electric Railway Company will be $5,300,000 for the present year, an increase of $550,000 over those of last year.

The National Carbon Company has declared a dividend of 2 per cent. on its common stock, an increase of one-half of 1 per cent. over the previous payment.

The Electric Storage Battery Company has declared the regular quarterly dividends of 1½ per cent. on its common and preferred stocks, both payable January 2.

The directors of the Bell Telephone Company of Philadelphia have decided to recommend to the stockholders that the capital stock of the company be increased from $16,000,000 to $30,000,000.

Judge Quarles, in the United States District Court at Milwaukee, has sustained the demurrer of the Milwaukee Electric Company of West Allis, Wis., against which a petition of involuntary bankruptcy was filed October 12 by Chicago and Milwaukee parties. The petition was dismissed.

The New Orleans Railways & Light Company has declared its first qarterly dividend under the reorganization of 1¼ per cent. on the preferred stock, payable January 15 to holders of record December 30. It is the policy of the company to hereafter declare quarterly dividends regularly at the same rate.

The Easton (Pa.) Consolidated Electric Company has levied an assessment of $5 a share on its stock, payable March 1. The company has also declared a dividend of $2.50 a share, payable on the same date. The dividend is to be credited by the treasurer on account of the assessment to holders of record February 17.

There is as yet no clear explanation of the minor details of the arrangement that will be made for the merger of the Interborough and the Metropolitan lines of New York. The reports heard in Wall Street are that the stock of the Metropolitan Securities Company, which now pays no dividend, was to be put on a 5 per cent. dividend basis and that the new holding company may take over the Securities Company stock by agreeing to pay this dividend. The same company could lease the Interborough lines by agreeing to pay a dividend rate on that stock acceptable to its holders. Any company taking over the Metropolitan Securities Company will have to assume all the obligations of that company, the chief of which is its guarantee of the Metropolitan Street Railways 7 per cent. dividend. Any permanent disposition that may be made of the Metropolitan Securities Company would apparently involve the calling of the balance of 50 per cent. that remains unpaid of the stock. It would thus be made full-paid stock instead of being subject, as it is now, to further assessments. The only official statement made about the merger is that no plans involving the traction companies would be consummated without affording every shareholder equal participation.

POSITIONS VACANT.

FREE ADVERTISING.

Inquiries from those seeking employment as Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or in other positions requiring technical experience or intimate acquaintance with the electrical trade, will be inserted in this column Without Charge. Each advertiser invited to repeat his advertisement in case the first one produces no results.

It is the desire of the management of this paper to bring the unemployed and employer together to their mutual benefit, and to this end they invite the former to make use of this column without charge. No advertisement exceeding five lines (about 25 words) will be inserted, but advertisers may write fully of their qualifications and these letters will be kept on file for future reference in filling vacancies which may occur.

Applicants should write clearly and distinctly and enclose postage to secure attention.

Address all communications to Free Advertising Editor, "Electricity," New York.

WANTED—Foreman of armature winding and assembling department of small motor works; good, steady position; state age, experience and salary desired. Address FOREMAN, care Electricity.

WANTED—Five salesmen to sell a well-known transformer; can be carried as a side line with non-competitive supplies. Address A. A. A., care Electricity.

SITUATIONS WANTED.

FREE ADVERTISING.

Inquiries from employers in want of Electrical Engineers, Superintendents, Foremen, Salesmen, Dynamo-tenders, Constructing and Designing Engineers, Electro-metallurgists, or other assistance from those possessed of technical experience in the various electrical lines will be inserted in this column Without Charge, whether subscribers or not.

Applicants should enclose the necessary postage to insure the forwarding of letters.

Address all communications to Free Advertising Editor, "Electricity," N. Y.

WANTED—Position as wire chief or manager; Is your service satisfactory? Is your exchange growing as it should? If not I can make it so. Eight years' of good practical experience. Present position wire chief. Address 352, care Electricity.

ANTED—Position by a young Japanese student in a small electric plant; salary no object. Address T. N., care Electricity.

WANTED—Position by a practical engineer and electrician; expert storage battery man and lead burner; direct or alternating; married; A1 references; would like medium central station or with a storage battery concern; moderate salary; sober. Address COMPETENT, care Electricity.

WANTED—Position by engineer-graduate with 9 years' experience in designing, manufacturing and marketing improved mechanical and electrical appliances; Chicago references. Address J. E., care Electricity.

WANTED—Position by a young man, age 21 years, in the office of a large electrical concern; one year sub-station experience; good knowledge of bookkeeping and electricity. Address E. M. C., care Electricity.

WANTED—Position with electrical company around electrical machinery or at installing and wiring; experienced at inside and outside wiring; age 21; student of International Correspondence Schools; can furnish references. Address J. H., care Electricity.

THE POOREST PART

No telephone is better than its poorest part. The secret of good telephone making lies in having every part as good as it should be.

Andrae Telephones

are well balanced. Each part has the quality it needs for the part it plays. In their make-up, nothing defective creeps in by mistake, nor to keep the cost down.

Andrae Telephones are made to satisfy, and the prices are very reasonable.

SOMETHING NEW.

In Line with the Twentieth Century Advancements of the World's Industries.

WHEN THE COVERS TO PRACTICAL ELECTRICITY ARE THROWN BACK

The Student, the Steam Engineer, the Practical Man, the Electrical Engineer and the College Professor see therein a new light, illuminating the way to an **easy and effective method** of studying the art of Electricity. The publishers have on file over four hundred letters, the writers ranging in rank from beginner **to noted Electrical Engineers,** commenting on the merits of this new work.

BOOK CONTAINS:

367 Pages of Subject Matter.

162. Pages Dictionary and Tables

427 Questions and Answers.

95 Illustrations.

30 Tables (all that's required).

Size 6 x 4½ inches.

Flexible Binding.

Set in 8 Point Type—a good, readable size

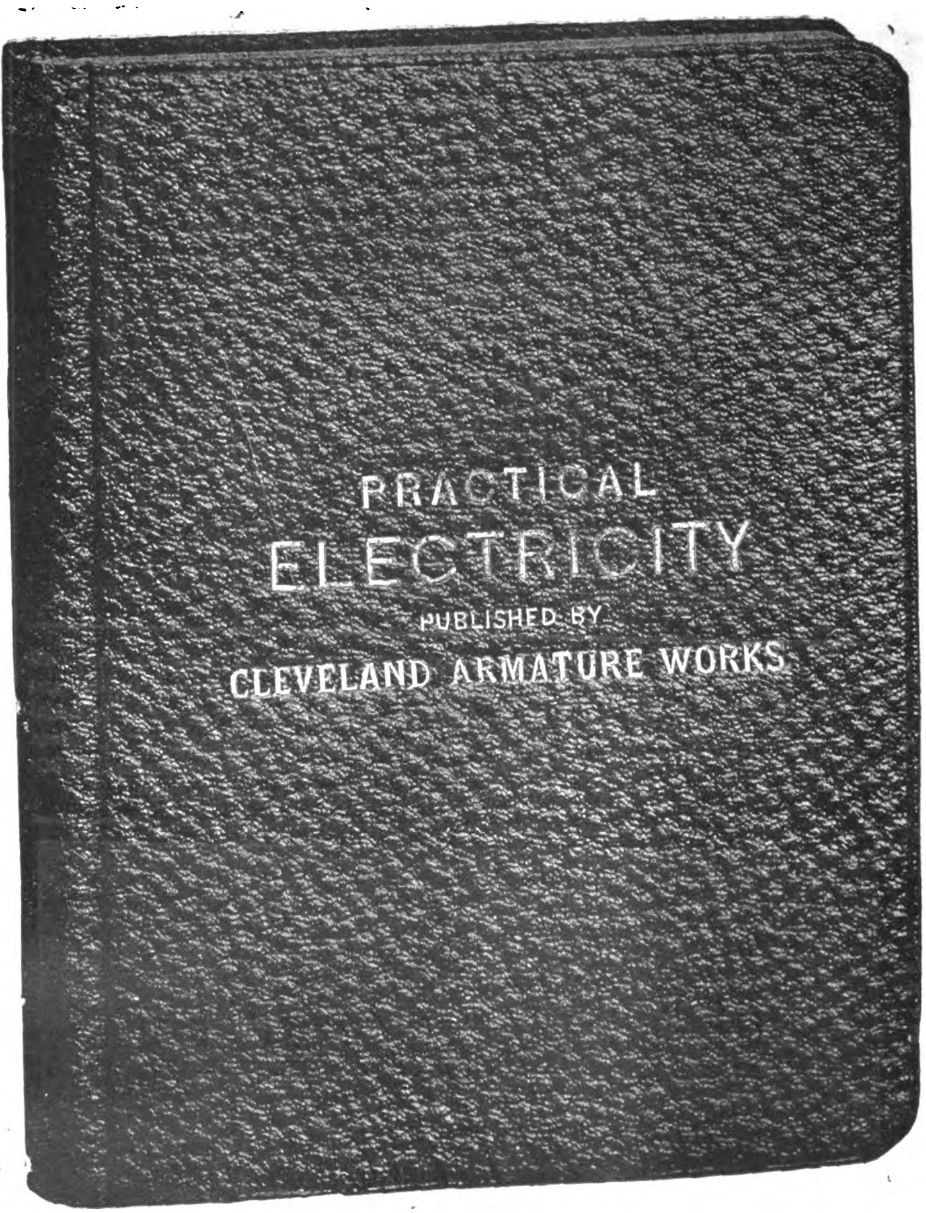

TABLE OF SUBJECTS:

Chapter.
I—Wiring.
II—Electric Batteries. Electric Plating.
III—Magnetism.
IV—The Magnetic Circuit.
V—Magnetic Traction.
VI—Magnetic Leakage.
VII—Energy in Electric Circuit.
VIII—Calculation of Size of Wire for Magnetizing Coils.
IX—Calculation of E. M. F.'s in Electric Machines.
X—Counter E. M. F.
XI—Hysteresis and Eddy Currents.
XII—Armature Reaction.
XIII—Sparking.
XIV—Winding of Dynamos and Motors.
XV—Proper Method of Connecting Dynamos and Motors—Self Excitation.
XVI—Diseases of Dynamos and Motors, their Symptoms and how to Cure Them.
XVII—Arc and Incandescent Lamps.
XVIII—Measuring Instruments.
XIX—Alternating Current.

A Dictionary of over 1500 Electrical Words, Terms and Phrases giving a brief meaning of all which are in common use.

Extracts of a few of the hundreds of Letters on file.

Geo. E. Hanscom, **Electrical Department** Mare Island Navy Yard, **says:** "Send two more copies of Practical Electricity. **Find this work invaluable.** I guess my friends do also as they never let a chance to steal them escape. I am having chains made to attach them to my desk."

Herbert W. Kimble, Electrician, Haverhill, Mass., says: "I saw in Dartmouth College Library a copy of Practical Electricity. I was so much pleased with it I want a copy."

L. D. Burlingame, Pasadena, Cal., says: "In a trip to Arizona I lost my copy of Practical Electricity. I prize the book so highly that I enclose money order for another."

Wm. Hickey, Sec'y Electrical Workers' Union No. 49, Chicago, Ill., says: "This book is a little wonder. Every Question and Answer is given so plainly that any one can understand them. It is not only instructive to beginners, but to those advanced as well."

Camble Courtney, Newry, S. C., says: "I know nothing about Electricity yet your book gives a great deal of valuable information, it is written in such a common sense way."

Lewis P. Osborn, Wardner, Idaho, says: "Mr. Livingston, Chief Electrician of the light plant at Bozeman, Mont., **gave me a copy of your book while I was in his employ.** I lost it in a hotel fire; find money order for another copy."

James H. Kendle, Marine Engineer, Detroit, Mich., says: "I purchased your book from **Burrows Bros.** of your city. **I think so much of the book. I have quite a library of books and have none I think more of than Practical Electricity."**

Price $2.00. Delivered. Third Edition. Address

SOMETHING NEW!

ELECTRICIANS' HANDY BOOK

By PROF. T. O'CONOR SLOANE, A.M., E.M., Ph.D.,

Author of "Arithmetic of Electricity," "Standard Electrical Dictionary," etc., etc.

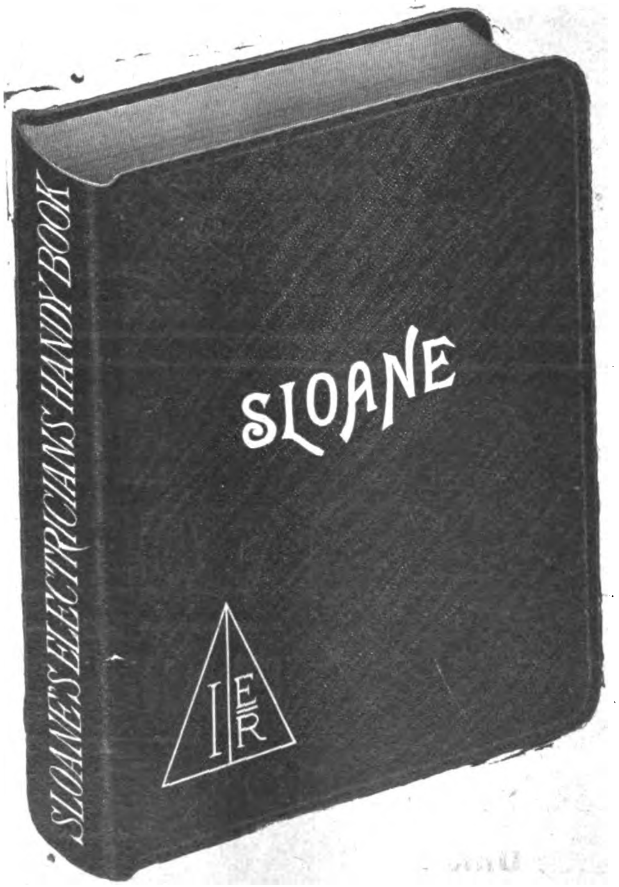
768 pages, 600 engravings. Handsomely bound in red leather, pocket-book style. Price $3.50.

A NEW BOOK FROM COVER TO COVER

A thoroughly practical book of 768 pages, covering the entire field of electricity. Contains no useless theory. Everything in it is to the point and can be readily understood by the student, the practical worker, and the every-day working electrician. The electrical engineer will also receive great benefit from its perusal and study.

It is a work of the most modern practice, written in a clear, comprehensive manner, and covers the subject thoroughly, but so simply that anyone can understand it fully. It teaches you just what you should know about electricity.

A practical work for the practical man which is without a peer. Contains 41 chapters, 600 engravings. It is the standard work on the subject. There is not a student, engineer, electrician, business manager or foreman who can afford to be without the information contained in its pages. You are doing yourself an injustice if you don't procure this book at once.



768 pages, 600 illustrations. Bound in red leather. Gilt edges. Pocket size, 4½x6¼.

CONTENTS

Chapter 1. Mathematics.
" 2. Electric Quantity and Current.
" 3. The Electric Circuit.
" 4. Ohm's Law.
" 5. Electro-Chemistry.
" 6. Primary Batteries.
" 7. Storage Batteries.
" 8. The Field of Force.
" 9. Magnets.
" 10. Induction.
" 11. Direct-Current Generators and Motors.
" 12. Direct-Current Armature Winding.
" 13. The Direct-Current Generator.
" 14. Armature Reactions.
" 15. Characteristic Curves.
" 16. The Direct-Current Motor.
" 17. Open Coil Generators.
" 18. Generators and Motor Construction.
" 19. The Alternating Current.
" 20. Alternating Current Generators.
" 21. Alternating Current Motors.
" 22. Transformers.
" 23. Management of Motors and Dynamos.
" 24. Care of Dynamos and Motors.
" 25. Station Notes.
" 26. Switchboards.
" 27. Voltmeters and Ammeters.
" 28. Distribution.
" 29. Lighting Arresters.
" 30. The Incandescent Lamp.
" 31. The Arc Lamp.
" 32. Photometry.
" 33. Electric Railroads.
" 34. Electrical Measuring Instruments.
" 35. Electrical Engineering Measurements.
" 36. Electroplating.
" 37. Electric Meters.
" 38. Telephony.
" 39. Bell Wiring.
" 40. Electric Heating.
" 41. Wireless Telegraphy.
